Given such fragmentation can we argue that there is a universal discipline of education such as in other areas of knowledge (e.g., medical knowledge)? Whitty and Furlong (2017) use a comparative analysis to explore what is understood as educational knowledge and whether such knowledge constitutes the discipline of education. They find that there are tensions that boil down to the purposes of education. In Germany for instance the definition of education as a discipline has benefitted from conceiving of education as deeply interdisciplinary which is seen as necessary to explain complex education issues—the insistence that this interdisciplinary composite or “science of education” is an autonomous discipline makes the German approach distinctive. In contrast in England, where the purposes of education are more practical—to prepare teachers for the job narrowly defined—allows more direct control from outside the profession and even from the markets. The conclusion is that education is constantly in tension between what national stakeholders require education to do such as inculcating values and attitudes or transmitting practical skills. The direction for England is currently dominated by the need to transmit practical skills which align with the dominance of the market model to education and is continuously reinforced by the OECD PISA test. Against this tendency toward convergence, however, the study highlights national variation as a source of strength, a finding that also emerged from an analysis of the U.S. decentralized system of education (Tatto and Clark, 2019).

Summary

The fragmentation of the education field in countries such as England and—less so in the decentralized system of the US—where the market has been allowed to operate, leaves the profession vulnerable to globalization trends and the influence of national populism movements that reject the value of theory and science, increase distrust in schools and teachers while introducing false narratives and divisiveness that seem directed at threatening democracy in possibly irreparable ways. The need to strengthen the teaching profession has never been more urgent.

Global instability: climate change, pandemic, conflict, migration

In parallel with the phenomena discussed in the previous two sections, the rise of neoliberal marketization and the growth of new manifestations of nationalism, we have seen evidence of growing instability around the world. So, in this section we consider the implications of climate change, the COVID-19 pandemic, social conflicts and migration. What impact do processes such as these have on schools and teacher education?

Climate change

The process of global warming has been linked to an increasing number of major environmental disasters, including floods, storms and fires. In many instances these have directly affected schools and other educational establishments. But the global effects of climate change pose a major threat to the existence of plant and animal species, including of course humans. What are the implications for teacher education and for the teaching profession? Much of the political action that has been undertaken in response to climate change has been led by young people in many parts of the world and the school strike actions, notably led by Greta Thunberg, have challenged schools, teachers and teacher educators in several countries. If children are absenting themselves from school to protest at the failure of their seniors to act on climate change, should teachers, student teachers and teacher educators offer their support? If school attendance is mandatory, then offering such support could be construed as an illegal act on the part of those adults (as well as the children). These are very real moral dilemmas for many professional educators.

Furthermore, what are the curriculum implications, both in schools and in teacher education programs, of global warming and climate change? And how can schools and universities reduce their carbon footprints to a minimum? To date there has been little evidence of significant educational responses to these challenges, with the exception of some environmental education initiatives and some significant developments in forms of outdoor and nature-based learning (Forest Schools for example, see [Knight, 2016](#); [Tiplady and Menter, 2021](#)). Even more radical arguments have been advanced at various times that schooling itself (and teacher education) is in some ways “anti-human” and destructive—ranging from Illich’s treatise on “deschooling society” ([Illich, 1971](#)) through to more recent accounts suggesting that children may be best educating themselves ([Gray, 2016](#)). Indeed, much contemporary conventional teacher education can be accused of leading to conformity and a kind of social stasis and/or reproduction ([Menter, 2016](#)).

Pandemic

The rapid spread of the COVID-19 virus around the world in 2020 had very direct impacts upon teacher education. Nearly every country around the world undertook various forms of “lockdown” in attempts to reduce the spread of the disease and to minimize the number of premature deaths. These lockdowns included the temporary closure of both schools and universities, the two key institutions involved in the provision of teacher education. Two aspects that arose are of particular significance in teacher education, the challenges to the “practicum” and the suspension of face to face teaching.

The practicum is universally seen as a core element of initial teacher education. Every ITE program in the world includes some element of school experience for the beginning teacher. Typically, the beginning teacher spends periods of time in school classrooms, taking increasing responsibility for teaching children, usually with the support of both teachers in school and of visiting staff from the university providing the program. The particular details and structures of the practicum vary enormously both between different national and state settings and even within these settings. However, it is a reasonable generalization to suggest that the beginning teacher’s performance in the school setting is assessed against a set of teaching standards or competences. That assessment is seen as a key indicator of that person’s preparedness to enter the profession as a qualified teacher. The challenge of completing a teacher education program when schools are closed was therefore considerable and led to some imaginative responses. In some settings even when schools reopened after a period of lockdown, there was great caution about allowing any “non-essential” personnel into the setting in the light of concerns about increasing the risk of the virus spreading.

The second key element of the effects of the pandemic was in relation to the mode of pedagogy deployed in teacher education. Students were not only unable to attend the practicum setting—the school experience—they were also unable to attend classes in their home university, as these institutions were also closed for lengthy periods. This led to a surge in the use of electronic, virtual means of communication. Various virtual learning environments (VLEs) were deployed, including Blackboard, Canvas, Webex and Minerva Collaborate. Other platforms were used for meetings and tutorials including Zoom, TEAMS and Skype. Such systems had

been in use in many contexts before the pandemic struck but the rapid expansion of their use during 2020 was quite phenomenal. The nature of the pedagogical relationships between teachers and learners was dramatically altered through the use of screens and the affective dimensions of interaction were shifted substantially with the reduced possibilities of effective non-verbal communication, usually a key element in learning, especially in one-to-one teaching situations.

Some of these issues arising from the pandemic are explored in more detail by teacher educators in special issues of two journals—see [Flores and Swennen \(2020\)](#) and [O'Meara and Hordatt Gentles \(2020\)](#). Reviewing the impact on the teaching profession in the UK of challenges such as those discussed above, [Breslin \(2021\)](#) suggested that:

In the main, school leaders, teachers and the wider school workforce, and those involved in initial and continuing teacher education, are emerging from lockdown with their professional status enhanced and a much richer public understanding of the complexity and range of the work that they do ...
[Breslin \(2021:152\)](#).

In similar vein and somewhat speculatively, in considering the provision of initial teacher education (ITE) “at scale,” Brooks concludes:

Much of the social media and educational press are speculating on what the impact of COVID-19 and the coronavirus are likely to be, including the impact on universities. Within England specifically, the status of teachers appears to be on the rise ..., and the demand for teacher education places is likely to grow as the effects on the wider economy are more broadly felt. Under these circumstances, questions of both quality and scale are likely to become more prominent.
[Brooks \(2021: 210\)](#).

Conflict and migration

Another aspect of global instability that may affect teacher education is the presence of political conflicts within societies. Thus, for example, we see that the disruptive effects of sectarian strife in Northern Ireland have meant that it has proved very difficult to reform and rationalize provision there, in spite of numerous reviews of teacher education and in spite of repeated efforts to integrate and bring harmony through curriculum reform ([Clarke and Magennis, 2016](#)). Physical violence directed toward teachers and teacher educators has been an issue in many divided societies, including South Africa, Syria and Afghanistan.

Conflict also frequently leads to forced migration, which can be another destabilizing global process. The movement of families and sometimes unaccompanied children across national boundaries is often a process fraught with difficulties, both physical and political. The arrival in schools of children who do not speak the national language can present particular challenges for teachers and for teacher educators. Furthermore, it is not uncommon for refugee communities to include teachers who are qualified in their country of origin. However, these qualifications are not always recognized in their country of arrival and so their potential contribution to the education service may be denied ([Kum et al., 2010](#)).

Summary

There is a continuing likelihood that processes such as those discussed in this section will lead to social inequality and injustice. While education cannot compensate for society ([Bernstein, 1970](#)) any more than teacher education can compensate for education, both schools and teacher education can play a part in addressing such social inequities. As Brooks has suggested in relation to teacher education:

Teacher education, with its complexity of stakeholders and interested parties, may be difficult to change, but teacher educators are adept at doing so, often navigating contradictory influences in order to provide the best possible experience for new teachers.
[Brooks \(2021:201\)](#).

Each of the global processes discussed here creates new demands on education systems and it is necessary for schools and teacher education institutions to respond positively to them. Some of the responses will be structural, for example expanding schools or teacher education programs, and some will be curricular, for example helping beginning teachers to understand the health risks associated with viral infections, helping them to model ecologically sound behavior for their students or developing skills in celebrating cultural and linguistic diversity.

Resources of hope: the contribution of comparative studies

One collection of essays written by the novelist and cultural theorist Raymond Williams was called *Resources of Hope* ([Williams, 1989](#)). Having previously set out early in the 1960s how he saw social progress in Britain as being a case of a “long revolution”

(Williams, 1961), Williams was becoming increasingly concerned about the growing impact of capitalism and the “free market” on culture and society (Williams, 1983). While he did not have a particular interest in teacher education, he did nevertheless see public education as a key plank in the development of democratic and equitable societies (see Menter, 2022a). In this section of our chapter, in the wake of our discussion of the impact of global turbulence on teacher education, as well as Brooks’ positive assessment just cited, of teacher educators’ ability to promote change, we turn to consider what resources of hope may be pertinent to the contribution that teacher education may make to social progress. We have already seen how a consideration of policies and practices in different geographical settings may enrich our understanding of teacher education and it is in the field of comparative studies that we may claim that many key insights are to be found.

The impact of neoliberalism has been pervasive in education systems around the world and this is no less the case in relation to teacher education (Tatto and Menter, *forthcoming*). Through studying the elements of professional knowledge that are deemed to be important we can detect the influence of national cultures and histories. This can be demonstrated in multi-nation states such as the United Kingdom (e.g., Teacher Education Group, 2016), in comparative studies of two countries (e.g., Tatto et al., 2018; Menter et al., 2017; Helgetun, 2022), as well as in comparative studies across many nations (Tatto et al., 2018, 2020; Tatto and Menter, 2019; Whitty and Furlong, 2017).

The foundations of comparative education were laid down in the 19th century and then developed in the 20th century by scholars such as Michael Sadler and Edmund King (refs). It was toward the end of the 20th century that significant developments took place in comparative research methodology (Crossley and Watson, 2013; Phillips and Schweisfurth, 2007) but also this was a time when there was increasing interest in teacher education, in part arising from the growing political priority being given to it. Mantras such as “the quality of an education system depend on the quality of the teachers working in that system” had great influence. Views of this kind were heightened by reports such as those undertaken by the McKinsey Corporation (Barber and Mourshed, 2007).

The “travel agent” of neoliberalism has been the process of globalization. Rizvi and Lingard (2010) and Spring (2015) have traced how the acceleration of communication processes and the influence of new forms of management have increasingly influenced policy and practice in education. But they also point out how this has not led to a simple convergence of approaches around the world. Rather, we can see distinctive forms of policy development emerging in a process that has been called vernacular globalization (Appadurai, 1996) or a coalescence of global and national characteristics—the “glonacal” (Marginson and Rhoades, 2002). A five-nation study of “culture and pedagogy” undertaken by Robin Alexander set new standards in the careful analysis of the relation between the two and made much reference to processes of teacher education (Alexander, 2000). Or in focusing on teacher education per se, a twelve-nation study examining knowledge, policy and practice in teacher education identified seven themes (one of which was added later) which could be used to delineate the particularities of each system within the wider global processes (Menter, 2019:272). These were:

1. The trajectory toward professionalization and “universitization” in teacher education—or its reverse.
2. The positioning of research in relation to policy and practice
3. Partnership and participants’ roles in teacher education.
4. Power and control, political structures, the relative influence of national/federal/state/regional/local institutions of government.
5. The impact of performativity and accountability and the promotion of standards in teaching.
6. The impact of digitization—technology and communication.
7. The links between pre-service, induction and continuing professional development—the teaching career continuum.

Each of these themes, when applied to a particular context, can tell us much about the condition of teacher education in that context.

However, it is not only in comparative work that we may gain important insights to the processes and politics of teacher education. Single nation studies can also demonstrate how developments and changes in one setting may have much wider significance. For example, Furlong’s analysis of “the university project” in teacher education in England (Furlong, 2013) shows how the connections between higher education and the education of schoolteachers is a critical factor—and this is relevant to any national setting. Or, in a review of teacher education in Russia, past, present and future (Menter 2022b), we can see how wider political changes such as the Russian Revolution of 1917 and the fall of communism late in the 20th century have had very significant impacts on policy and practice.

Reviewing policy processes in teacher education around the world, it is a challenge to find powerful examples of instances where teacher education has taken the lead in the development of democracy or the creation of more socially just societies. There are many more local examples of democratic practices being implemented in schools and local communities than in teacher education. And many of these examples have attracted opposition from the forces of the state. One might cite the work of Paulo Freire in rural settings in Brazil, which not only led to improved literacy but to campaigns for improved working conditions, leading to Freire being exiled (Collins, 1977). In the US, Apple and Beane (1999) documented a number of cases where radical innovation in the cause of “democratic schooling” was undertaken, frequently leading to ostracism from politicians. It is all too rare to find similarly radical approaches being introduced in teacher education, especially in the 21st century as we have seen in so many instances the impact of central or state government’s “tightening grip” (Childs and Menter, 2013).

Given the tendency toward conformity and social reproduction that is evident in so many systems of teacher education, the importance of comparative study cannot be underestimated. An analysis of the links between culture, politics and history is crucial

to developing our understanding and to informing policy development. There is a need for close links between the respective communities of policy, practice and research in teaching and teacher education. These links are currently much stronger in some places than in others and indeed the use of “evidence” remains a highly significant and often contested aspect of these processes (Helgetun and Menter, 2020).

Conclusion

In this chapter we have sought to understand how teacher education has been changing—and continues to change—during a period of considerable global instability. The economics, politics and cultural traditions within any particular context have shaped the patterns of provision and influenced policy and practice. We have seen how some influences occur at a global level, others are at national, institutional and even personal level (Tatto et al., 2018, explores this view more fully). However, a central message to be derived from our analysis is that investigation of any particular system will be greatly enhanced by ensuring that comparisons are made with other settings. It is through a comparative lens that we can begin to appreciate the interplay of structure and agency in the world of teacher education. We can begin to explore how it may be possible for those with specialist expertise and experience within teacher education to bring those assets to bear in the development of policy and of practice globally. In our own work we have found that a particular sociocultural research methodology may be especially powerful in highlighting the key processes that are at work in the field of teacher education (Burn and Menter, 2021).

If teacher education is to make a continuing contribution to global stability, peace and democracy around the world, then there is a great need, indeed it is essential that we see a growth of independent critical research, including much that is comparative in nature. In this rapidly changing world with the overbearing threats from climate change, the rise of new forms of populism and nationalism, continuing conflicts and strife, and associated migrations of populations, we will need policy and practice in teacher education to be informed by high quality research as well as by the professional judgment of experienced practitioners in the field. This will be as important in western, “advanced” nations, where much provision will continue to be at a large scale (Brooks, 2021), as it will be in recently democratized nations and those going through major economic, social and political change, as in the case of the BRICS nations (Brazil, Russia, India, China, South Africa), and many others. (An International Research Network of the World Educational Research Association was established in 2021 to coordinate research on teacher education in this group of nations.)

The overall impact of the neoliberal processes of marketization and performativity have undoubtedly caused considerable damage to the best features of teacher education systems in many parts of the world. It will be through a combination of professional agency and the achievement of continuing high-quality research that we may hope to see significant improvements in what is being offered and what is being realized in these systems. The global pandemic of 2020/21 has revealed not only the vulnerability of teacher education but also the great imagination and potential power of those teachers and teacher educators working within the field. Our resources of hope for the future lie with these colleagues and in the comparative research that must continue to be undertaken.

EDITORS IN CHIEF – BIOGRAPHIES

Robert J Tierney

Rob Tierney is an international educator whose passion is for developing research partnerships to address local literacy needs with educators in different countries. Rob began his career as a classroom teacher in Australia, then proceeded to work in the United States, Canada, Australia and China. He is Dean Emeritus and Professor Emeritus of Language and Literacy Education at the University of British Columbia, the former Dean and Honorary Professor of the Faculty of Education and Social Work at University of Sydney, and a Distinguished University Professor at Beijing Normal University. In the United States, he has served on the faculties of the University of Illinois, University of Arizona, The Ohio State University, Harvard University, and the University of California. Rob has written a number of books and numerous articles on literacy especially related to global issues, diversity, and literacy development. His most recent book was entitled *A History of Literacy Education: Waves of Research and Practice* published by Teachers College Press in 2021. During his tenure as an educator, he has served as the President of the International Literacy Association, President of the Literacy Research Association, an Editor for the *Reading Research Quarterly*, the President of the Association of Canadian Deans of Education/ L'Association Canadienne des Doyens et Doyennes d'éducation, as well on a number of committees and boards for professional groups and government and nongovernment

agencies. In addition, he has been involved on a range of groups on projects globally including in Africa and Asia including for UNESCO, Children's Television Workshop, and Apple Computer.

Fazal Rizvi

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely, and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge 2010) is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge 2022) has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

**Kadriye Ercikan**

Kadriye Ercikan is Vice President of Research and Measurement Sciences at the Educational Testing Service and Professor Emerita at the University of British Columbia. She is responsible for ETS's foundational and applied research and psychometric support of ETS's major testing products and contracts, and the NAEP contract for ETS. Her research focuses on validity and fairness issues and sociocultural context of assessment. Her recent research includes validation of score meaning using response processes, use of response process data for comparing groups and examining fairness and validity of interpretation, and use of scores from artificial intelligence-based automated scoring.

Ercikan is a Fellow of the International Academy of Education. Her research has resulted in 6 books, 4 special issues of refereed journals, and over 100 publications. She was awarded the AERA Division D Significant Contributions to Educational Measurement and Research Methodology recognition for another

coedited volume, *Generalizing from Educational Research: Beyond Qualitative and Quantitative*

Polarization, and received an Early Career Award from the University of British Columbia. Ercikan has been selected to serve as the NCME Book Series Editor (2021–2026).

SECTION EDITORS

Jason Beech is Associate Professor (Global Policy) at the University of Melbourne and visiting professor at Universidad de San Andrés in Buenos Aires where he holds a UNESCO Chair in Education for Sustainability and Global Citizenship. He is senior researcher of the National Council for Scientific and Technical Research of Argentina (CONICET), and Associate Editor of *Education Policy Analysis Archives*. He has been a member of the Board of Directors of the Comparative and International Education Society (2014-2016). Jason has published extensively on the globalization of knowledge and policies related to education. He has also written and is passionate about the challenges of educating for global citizenship and a sustainable future. He has taught in several universities in the Americas, Europe and Australia.

Professor Qing Gu is Director of the UCL Centre for Educational Leadership and Professor of Leadership in Education. She is the Past Chair of the *British Association of Comparative and International Education* (BAICE), Co-Editor of *Teachers and Teaching: Theory and Practice*, Associate Editor of *International Journal of Educational Development*, a member of the Research Standing Committee of the World Council of Comparative Education Societies (WCCES), and a member of the Research Evidence and Impact Panel for the Leadership College for UK Government. Professor Gu has directed and codirected many government and research council funded projects in the areas of teacher professional development, school improvement, and systemic reform and change. She has led a £1.9 m UK Economic and Social Research Council (ESRC) funded project *Schools as Enabling Spaces to Improve Learning and Health-Related Quality of Life for Primary School Children in Rural Communities in South Africa*. Some of her books have been translated into Chinese, Japanese, and Spanish.

Professor Smith is a New Zealand Maori of Te Aitanga a Hauiti, Ngati Porou, Kati MamoeNgati Apa, Ngati Kahungunu descent. He is a highly regarded and internationally recognized, Maori educationalist and scholar. He has been at the forefront of transforming Maori and Indigenous social, economic and cultural conditions through re-developing education and schooling outcomes. His work links theoretical thinking and practical applications within an ongoing cycle of transforming praxis.

Professor Smith trained as a teacher at Auckland Teachers College and taught in Auckland schools. He also lectured in Education at the Auckland College of Education. He was one of the first teachers and developers of a Kura Kaupapa Maori, an alternative, Maori philosophy and principles-based School. These Maori immersion schools have grown from a single entity in 1988 to over seventy-five publicly funded schools in 2015. His theoretical leadership in the Education Department at the University of Auckland helped inform the emergence of Maori Education as a distinct field of study across the New Zealand Tertiary Sector. This work has encouraged a wide range of academic studies focused on overthrowing persisting inequities within and as a result of education and schooling in New Zealand. His significant contribution to New Zealand education is to be seen in his work related to Kaupapa Maori as a theory of Transformative Praxis. All of these elements derive from his PhD research entitled, "The Development of Kaupapa Maori: Theory and Praxis (1997)".

Professor Smith's later academic work centered on developing theoretically informed strategies related to transforming high and disproportionate levels of Maori cultural, political, social, educational, and economic marginalization. He has been a significant scholar involved in the emergence of Tribal "universities" institutions (Wananga) and is the former foundation Chair of the Council for Te Whare Wananga O Awanuiarangi. He led the successful Treaty of Waitangi Claim and settlement for Awanuiarangi. In his former position as Pro Vice Chancellor (Maori) at the University of Auckland, he was responsible for developing significant structural change within the institution while working within the Office of the then Vice Chancellor, Dr. John Hood. Notable achievements included implementing a Maori development strategy within the University which required all Deans to be responsive in their performance results for Maori and Pacific advancement; the oversight of the Proposal and winning of a National Centre of Research Excellence (Nga Pae o te Maramatanga); the initiation of the Maori and Indigenous doctoral program aimed at creating 500 Maori PhD graduates across the country in five years; the recruitment of top Maori academic scholars into the University of Auckland; the development of Kaupapa Maori as a theory of transformative praxis and which has had national and international influence. Professor Smith also served on the University of Auckland Council for three years as the Professorial representative for Academic staff.

In 2007 Professor Smith accepted a role as the Universitas 21 Distinguished Visiting Professor in Indigenous Education hosted by the University of British Columbia (within the Faculty of Education). Although the position was initially intended for two years, the role was extended for a further three years. While situated at the University of British Columbia, Professor Smith also chaired the Educational Policy Studies Department for three years. These positions allowed engagement with many Canadian universities as well as other universities across the world.

Professor Smith has made significant contributions to the political, social, economic, and cultural advancement of Maori and indigenous communities in New Zealand and around the Pacific Rim. He has worked extensively with other Native/Indigenous/First Nation's peoples across the world, including in Canada, India, US mainland (including extensive work in Hawaii and Alaska), Norway, Taiwan, Chile, Australia, as well as with selected Micronesian and Pacific nations. He is a regular contributor to national and international forums and conferences. Professor Smith has been an authoritative voice within the critical debates on *social, cultural and economic inequality* both in New Zealand and abroad, and he maintains a strong influence in the Maori/Indigenous languages revitalization movements.

Professor Smith stepped down from the administrative position of CEO/Vice Chancellor at Te Whare Wananga o Awanuiarangi in 2015 after eight years in the role. He resumed his academic research and writing career. In 2019 he was invited to take up a special Chair – Te Toi Ihorei ki Purehuroa – A "distinguished Professorial position at large" established for him at Massey University.

Professor Smith has been recognized and honored for his international contributions, receiving an Honorary doctorate (D.Litt.) from the Okanagan University College in 2005, and an Honorary doctorate (LLD) from the University of Northern British Columbia in 2013; he was elected as a Fellow of the American Education Research Association in 2014, and was awarded a Queens Honour – a CNZM in 2014. He was given the Prime Minister's Life-time Achievement Award (2017); and received the Te Ururangi National Award for Education (Matariki Awards, 2019).

Professor Smith is married to Professor Linda Tuhiwai Smith and they have one daughter and two mokopuna (grandchildren).

Therese N. Hopfenbeck is Professor of Measurement Analytics in the Melbourne Graduate School of Education, The University of Melbourne. Before starting her position in Melbourne, she was Professor in Educational Assessment and Director of the Oxford University Centre for Educational Assessment. She is a Visiting Fellow at Kellogg College, University of Oxford, elected Vice-President of *The Association for Educational Assessment-Europe* and Lead Editor of the journal *Assessment in Education, Principle, Policy and Practice*. Dr. Hopfenbeck's research agenda focuses upon bridging research on self-regulation and classroom-based assessment and making sense of international large-scale studies in education. In collaboration with Professor Nancy Perry, University of British Columbia, she is currently leading an international network of researchers disseminating classroom-based research, funded by Social Sciences and Humanities Research Council of Canada (2020–2022). She is also currently Principal Investigator for two research projects funded by IB, on critical thinking in PYP schools internationally and evaluation of education reforms in Kent, UK (2020–2022). In 2020, she led the research on Critical Thinking in the Diploma Program in Australia, England, and Norway (<https://ibo.org/research/outcomes-research/diploma-studies/critical-thinking-skills-of-dp-students/>). Dr. Hopfenbeck was Principal Investigator for the PISA (2022) study in England, Northern Ireland, and Wales, in collaboration with Pearson UK (2018–2023). She was the Research Manager of PIRLS (2016), funded by The Department of Education, UK.gov, and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019). Since coming to Oxford in 2012, she has been the recipient of funding from ESRC-DFID, OECD, The Norwegian Research Council, Education Endowment Foundation, State Examinations Commissions Ireland, Jacob Foundation, and the International Baccalaureate totaling more than £2 mill in addition to a single grant of £4 mill in collaboration with SLATE: Centre for the Science of Learning & Technology at the University of Bergen, Norway. Prior to her appointment at Oxford, she worked as a postdoctoral researcher at the University of Oslo's research group for Measurement and Evaluation of Student Achievement at the Unit for Quantitative Analysis of Education (2010–2011). She is Adjunct Professor of the Norwegian University of Science and Technology (NTNU), member of the Visiting Panel for Research at the Educational Testing Service (ETS) in Princeton, expert member of the PISA (2022) Questionnaire Framework group, appointed by ETS and OECD (2014–2023). She has advised on the implementation of formative assessment programs in India, South Africa, Norway, and the Emirates and carried out policy work for UNESCO/OECD and the Norwegian Ministry of Education Norway. Therese has a presence on LinkedIn, ResearchGate, [Academia.edu](https://www.academia.edu/), and Twitter: @TNHopfenbeck.

tion, [UK.gov](https://www.uk.gov/), and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019). Since coming to Oxford in 2012, she has been the recipient of funding from ESRC-DFID, OECD, The Norwegian Research Council, Education Endowment Foundation, State Examinations Commissions Ireland, Jacob Foundation, and the International Baccalaureate totaling more than £2 mill in addition to a single grant of £4 mill in collaboration with SLATE: Centre for the Science of Learning & Technology at the University of Bergen, Norway. Prior to her appointment at Oxford, she worked as a postdoctoral researcher at the University of Oslo's research group for Measurement and Evaluation of Student Achievement at the Unit for Quantitative Analysis of Education (2010–2011). She is Adjunct Professor of the Norwegian University of Science and Technology (NTNU), member of the Visiting Panel for Research at the Educational Testing Service (ETS) in Princeton, expert member of the PISA (2022) Questionnaire Framework group, appointed by ETS and OECD (2014–2023). Therese has a presence on LinkedIn, ResearchGate, [Academia.edu](https://www.academia.edu/), and Twitter: @TNHopfenbeck.

Nataliya Ivankova, PhD, MPH, is Professor in the School of Health Professions at the University of Alabama at Birmingham (UAB). As an applied research methodologist working at the intersection of mixed methods, qualitative, community-based, action, and translational research, she is internationally recognized for her empirical and methodological publications. She shares her research expertise through teaching mixed methods and qualitative research courses, conducting workshops and guest lectures, mentoring doctoral students and junior faculty, and serving as key personnel on funded research projects. At UAB, she directs an online graduate certificate program in *Applications of Mixed Methods Research* and oversees the design and analytical aspects of qualitative and mixed methods studies through the Center for Health Informatics for Patient Safety and Quality. She is a founding Coeditor of the *Mixed Methods Research Series* (Sage) and serves as an Associate Editor for the *Journal of Mixed Methods Research*.

Professor Jahnke is Director of Toi Kura Centre for Maori & Indigenous Education. She was the 2019 inaugural Toi o Te Wananga Fellow. Professor Jahnke holds professional qualifications in education and is cofounder and immediate past Chair of the Indigenous Peoples of the Pacific Special Interest Group of the American Education Research Association (AERA). She currently serves on the AERA Executive Committee. She was a member of the Social & Human Sciences Sub Commission of the NZ National Commission for UNESCO, the NZ Bioethics Council, the NZ Ethics Committee on Assisted Reproduction Technology, and Chair of NZ Health Research Council Ethics Committee. She is currently Cochair of the Aotearoa Research Ethics Board and a Fulbright Scholar.

Berit Karseth, PhD, is Professor at the University of Oslo, Department of Education. Karseth's main research and publications lie in the field of education policy, reforms, and curriculum studies. She has edited four books and written several journal articles and book chapters in both Norwegian and English. Her most recent publications in English include articles published in the *Journal of Education Policy*, *Scandinavian Journal of Educational Research*, *Journal of Curriculum Studies*, and *European Educational Research Journal*. Karseth was the elected dean of the Faculty of Educational Sciences at the University of Oslo 2013–2016 and is currently in the leadership team of the research group Curriculum studies, educational leadership, and governance (CLEG) at the same institution.

Dr. Kenneth Leithwood is Emeritus Professor at OISE/University of Toronto and an honorary professor at the University College London and the University of Nottingham. His research and writing is about school leadership, educational policy, and organizational change. He has published extensively on these topics. For example, his most recent books include *Leadership Development on a Large Scale: Lessons for Long-term Success* (2018, Corwin), *How School Leaders Contribute to Student Success* (2017, Springer), and *Linking Leadership to Student Learning* (2012, Jossey Bass). Professor Leithwood is the inaugural recipient of the University of Toronto's *Impact on Public Policy* award, AERA (2011) *Outstanding Leadership Researcher Award*, the 2012 *Roald F. Campbell Lifetime Achievement Award* from the University Council for Educational Administration, and the Ontario Principals' Council *Outstanding Educator of the Year* award for 2017. He is a *Fellow of the Royal Society of Canada*. A recently published bibliometric analysis found that Dr. Leithwood was the most frequently cited, highest impact educational leadership researcher in the world.¹ Research.com's 2022 Ranking of the Top 1000 Scientists in the area of Social Sciences and Humanities ranked Dr. Leithwood 70th in the world and 7th in Canada.

Xiufeng Liu is a Professor of Science Education at State University of New York, Buffalo, and a Fellow of the American Association for the Advancement of Science (AAAS). He obtained his PhD from the University of British Columbia in 1993. Before his current position, he taught high school chemistry in China, and was a tenured faculty member at St. Francis Xavier University and University of Prince Edward Island, both in Canada. From September 2020 to August 2022, he served as a program director in the Division of Research on Learning of the National Science Foundation. Dr. Liu conducts research on measurement and evaluation of STEM education and student learning of cross-cutting concepts of matter and energy. Dr. Liu is currently a Coeditor-in-chief for the journal *Disciplinary and International Science Education Research* (Springer) and an Associate Editor for the *Journal of Research in Science Teaching*, a premier journal in science education.

Margie Maaka is a Professor of Education at the University of Hawai'i at Mānoa. Her PhD is in educational psychology. She also holds professional qualifications in education from the University of Waikato and Hamilton Teachers College. She is cofounder and current Program Chair of the Indigenous Peoples of the Pacific Special Interest Group (SIG) of the American Educational Research Association (AERA). From 2017 to 2020, she served as a member of the AERA Executive Council and Chair of the SIG Executive Committee. Before that (2014–2017), Professor Maaka served as a member of the SIG Executive Committee. She has also served as a member of the Ngā Pae o te Māramatanga Center of Research Excellence International Research Advisory Panel. Her research on community-based educational renewal saw her recognized as a national scholar with the Goodlad Institute for Educational Renewal. As Cochair of the Sovereign Councils of the Hawaiian Homelands Assembly's Committee on Education, she prepared educators and educational leaders for public schools in the Hawaiian Home Lands Trust communities. Currently, Professor Maaka is committed to the preparation of indigenous educational leaders in higher education. Her research interests include community partnerships, educational psychology/indigenous educational psychology, indigenous development and advancement, educational policy, multiliteracies, and language and cognitive development.

Diane Mayer is Professor Emerita at the University of Oxford. Her research and scholarship focus on teacher education and early career teaching, examining issues associated with the policy and practice of teachers' work and teacher education.

Daniel McCaffrey is the Associate Vice President of Psychometric Analysis and Research in the Research and Measurement Science unit of the Research and Development division at ETS. Dan's research interests include the evaluation of artificial intelligence scoring of constructed responses, developing tools and methods for causal modeling, evaluating the psychometric properties of student achievement growth measures derived from annual test scores, and methods to account for measurement error in secondary data analysis. Dan received his PhD in Statistics from North Carolina State University in 1991.

Judy Parr is Professor Emerita at the University of Auckland, Faculty of Education, where she was the founding Head of the School of Curriculum and Pedagogy. A psychologist, Dr. Parr's research program is located broadly within improvement science. Her expertise is in literacy, specifically writing and its development, encompassing instructional issues like teacher knowledge and practice and the assessment of writing. Much research has been collaborative, with colleagues and practitioners within major national projects for school improvement aimed at raising achievement in literacy and, internationally, as part of funded large-scale research projects, for example in Canada and Norway. Dr. Parr has published widely in the areas of literacy, assessment, and professional learning.

Jeong-eun Rhee is a Professor of Education, Long Island University, Post, New York. Born and raised in Seoul, Korea, she earned her bachelor's degree in Educational Psychology from Ewha Women's University. In 1992, she came to the US as an international student and received an MA in Educational Psychology from West Virginia University and a PhD in Educational Policy and Leadership from the Ohio State University. As an interdisciplinary cultural researcher and educator, her recent work focuses on developing and supporting transnational, intergenerational, and decolonial feminist knowledge projects in/through antioppressive education. She recently published *Decolonial Feminist Research: Haunting, Rememory, and Mothers*, which received an honorable mention for the 2022 Qualitative Book Award of International Congress of Qualitative Inquiry.

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge, 2010), is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge, 2022), has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

Theresa Rogers is Professor of Language and Literacy Education at the University of British Columbia. Her research interests include youth arts, media and critical literacies, adolescent literature, and teacher education in literacy. Most recently she published "Youth Activism through Critical Arts, Transmedia, and Multiliteracies" in the *Oxford Research Encyclopedia*. She is author of the book, *Youth, Critical Literacies and Civic Engagement: Arts, Media and Literacy in the lives of adolescents* (Routledge) and numerous articles in scholarly journals such as *Literacy Research: Theory, Method and Practice*, *Reading Research Quarterly*, *Pedagogies*, *Language Arts*, *Children's Literature in Education* and *Journal of Literacy Research*. See: <https://ubc.academia.edu/TheresaRogers>.

Professor Chika Sehoole is a Professor of Higher Education and the Dean of the Faculty of Education at the University of Pretoria. He obtained his PhD at the University of the Witwatersrand, Johannesburg, in December 2002. In 2003/4 he was a visiting Rockefeller postdoctoral fellow at the Centre for African Studies at the University of Illinois in Urbana Champaign. In 2005/06 he was a New Century Fulbright Fellow, again, at the same university. His research interests are in the areas of higher education policy, internationalization of higher education, higher education in Africa, and teacher education. He has served in several international research projects focusing on higher education and providing expertise from the South African and African perspectives. In 2013–2017 he served as the Chairperson of the Board of the African Network for Internationalisation of Education (ANIE). He currently serves as the chairperson of the Education Deans' Forum of South Africa. He has published a singled authored book titled "Democratising higher education policy, constraints of reform in post-apartheid South Africa" by (Routledge); three edited scholarly books on higher education and more than 40 articles in journal articles, book chapters, and popular media.

Roland Sintos Coloma is a tenured Full Professor of Teacher Education at Wayne State University in Detroit, Michigan. A scholar of history, cultural studies, and education, his research addresses critical questions of race, gender, and sexuality from transnational and intersectional perspectives. His publications include *Asian Canadian Studies Reader* (2017), *Filipinos in Canada: Disturbing Invisibility* (2012), and *Postcolonial Challenges in Education* (2009). His articles have been published in top-ranked peer-reviewed journals, including *Curriculum Inquiry*, *Discourse: Studies in the Cultural Politics of Education*, *Educational Studies*, *Educational Theory*, *History of Education Quarterly*, *International Journal of Qualitative Studies in Education*, *Paedagogica Historica*, and *Race Ethnicity and Education*. He has successfully garnered over \$2 million of external funding from federal, education, and nonprofit agencies, including the US Department of Education, National Education Association, Spencer Foundation, and Schultz Family Foundation as part of the Bill & Melinda Gates Foundation's Grand Economic Challenges. Roland has served in various university leadership roles as an assistant dean, department chair, graduate coordinator, and center codirector. He was president of the American Educational Studies Association (2018–19), editor of the *Educational Studies* journal (2014–17), and program cochair of Division G (Social Context of Education) in the American Educational Research Association (AERA). He received the 2017 Distinguished Scholar Award from the AERA Research on the Education of Asian Pacific Americans SIG and the 2015 Article of the Year Award from the AERA Queer Studies and Education SIG. In 2020, he was appointed to the Governor of Michigan's statewide Asian Pacific American Affairs Commission. Born in the Philippines and raised in California, he completed his PhD in Cultural Studies in Education and Minor in African American and African Studies from The Ohio State University in 2004.

Roger Slee is the Founding Editor of *The International Journal of Inclusive Education* and *The Journal of Disability Studies in Education*. A former Deputy Director-General of Education in Queensland, Australia, he has advised governments on inclusive education policy and practice. His published books include: *The Irregular School*; *Inclusive Education Isn't Dead, It Just Smells Funny*; and *Ethics and Inclusive Education: Disability, Schooling & Justice* (with Gordon Tait). Roger was commissioned by the UNESCO to write the scoping paper for the 2020 Global Education Monitoring Report, *Inclusion and Education*. Roger also held the Chair of Inclusive Education at the Institute of Education, London, and is now the Diamond Jubilee Professor of Disability & Inclusion in the School of Sociology & Social Policy at the University of Leeds.

Ninni Wahlström is a Professor of Education at Linnæus University, Sweden. Her current research focuses on transnational and national policy discourses and their implications for national curriculum and classroom teaching from a perspective of curriculum theory and educational philosophy. Most recent publications are "School and democratic hope: the school as a space for civic literacy" in *European Educational Research Journal* (2022) and Wahlström (Ed.) *Equity, Teaching Practice and the Curriculum*, Routledge (2022).

Lei Wang is Professor and PHD advisor of the Institute of Chemical Education, the College of Chemistry in Beijing Normal University (BNU). She is also the member of Teaching Steering Committee on Basic Education of Ministry of Education of China and the director of its branch Committee on Secondary Chemistry Education, the director assistant of Faculty of Education of BNU, vice director of the Institute of Science Education of BNU, and Chairman of the Chemistry Education Committee of the Chinese Chemical Society. She is one of the chief experts in developing the *Secondary School Chemistry Curriculum Standards* of MOE. She works as the chief editor of high school chemistry textbooks (Shandong Science and Technology Press, 2004 and 2019 editions) and junior high school chemistry project-based learning textbooks (Shanxi Education Press, 2018 edition). She achieved the first prize of the National Basic Education Teaching Achievement Award, the second prize of the National Higher Education Teaching Achievement Award, and the BAOGANG Education Outstanding Teacher Award.

Everard Weber is a retired professor. He has worked in the field of education for more than 40 years. Currently he is a research associate at the University of Johannesburg (UJ) and an academic advisor in the Future Professors Programme (FPP) at UJ. He studied African Languages and History at the University of Cape Town and Comparative and International Education at Harvard University. In South Africa he has worked at Crestway High School in Cape Town, the University of the Witwatersrand, and the University of Pretoria. A recent book is *A home away from home: a community of international and South African university students*. The FPP is a government-sponsored initiative that seeks to develop the next generation of professors and academic leaders in all disciplines, across all universities in South Africa. He is in addition presently conducting fieldwork on curriculum change in South African higher education with Professor Shireen Motala and Dr. Venise Joubert at UJ. This project is grounded in the history of southern Africa and hopes to contribute to the scholarship of postcolonialism.

Ian A.G. Wilkinson is Professor in the Department of Teaching and Learning at The Ohio State University and Honorary Professor in the School of Curriculum and Pedagogy at the University of Auckland, Aotearoa/New Zealand. He has a background in educational psychology with special interests in cognition, instruction, and research methodology as they relate to the study of literacy. He served as coauthor of the influential report, *Becoming a Nation of Readers* (National Academy of Education, 1985). He was Co-Editor of *Reading Research Quarterly* from 2006 to 2012 and was inducted into the Reading Hall of Fame in 2021. His research examines the impact of classroom discussion and dialogue on students' reading comprehension and argument literacy and the implications for professional development of teachers. Recently he coauthored books include *The Most Reasonable Answer: Helping Students Build Better Arguments Together* and *Quality Talk About Text: Discussion Practices for Talking and Thinking About Text*.

David B. Yaden, Jr., PhD, is the *Jewell M. Lewis Endowed Distinguished Professor of Literacy* in the Department of Teaching, Learning and Sociocultural Studies at the University of Arizona. Prior to his present position at the University of Arizona, he held appointments at Emory University, the University of Houston, and the University of Southern California. He served as Co-Editor of the *Journal of Literacy Research*, one of the premier research journals in the field of literacy studies, and was a Principal Investigator in the federally funded Center for the Improvement of Early Reading Achievement (CIERA) where he implemented an early literacy curriculum for linguistically diverse preschoolers in inner-city Los Angeles. He also directed a statewide consortium of researchers from Arizona's major universities in the evaluation of the state's early childhood initiative to evaluate health, developmental, and educational factors contributing to school readiness. His research interests and specializations include developmental issues in early childhood education, the acquisition of literacy and biliteracy in young emergent bilingual children, family literacy, theories of reading disability, microgenetic research design, and the application of complex adaptive systems theory to growth in reading and writing.

Volume 6: Learning, Cognition, and Human Development

Ian A G Wilkinson and Judy M Parr

© 2023 Elsevier Ltd. All rights reserved.

Introduction

Confronted with the task of assembling some 80 chapters for the volume on *Learning, Cognition, and Human Development*, we sought guidance (and solace) in the work of our predecessors, as well as others. We scoured the pages of the corresponding volume, titled *Learning and Cognition*, of the previous edition of the *IEE*. We pored over the contents of contemporary handbooks with related titles: handbooks in educational psychology, cognition, motivation and learning, cognitive processes, learning and instruction, and the learning sciences. We dutifully perused topics in related encyclopedias in education, educational psychology, and human development. What we were searching for was some form of conceptual framework to guide our selection and organization of topics. We did not find it or, if it was there, we did not see it.

A breakthrough, of sorts, came when we consulted the recently published report from the [National Academies of Sciences, Engineering, and Medicine \(2018\)](#), *How People Learn II: Learners, Contexts, and Cultures*. This report surveyed research on fundamental processes in the individual that impact learning (as did the earlier *How People Learn: Mind, Brain, Experience, and School*, [National Research Council, 2000](#)), but it also examined the influence of culture in shaping how people learn and the nature of learning over time. Internal processes involving knowledge, mental models, reasoning, and the like are important for learning, but they are shaped by contexts and cultures, and the way they function changes throughout a person's life span.

At the outset, then, we took learning as the primary conceptual construct to frame this volume (it is, after all, at the forefront in the title). Following the framework implicit in *How People Learn II*, we organized the content using the tripartite division of people, space, and time. From this, we derived our three core sections: *The Learner: Fundamental Processes*, *Learning in Contexts and Cultures*, and *Learning Over Time*. We bookended these core sections with a front section titled *Perspectives on Learning: Theory and Methods* and a back section titled *Optimizing Learning*. Our intention with the latter was to survey current interventions and pedagogical approaches that research suggests have the potential to optimize learning in formal (i.e., school) and informal settings, including digital environments.

Having arrived at a conceptual framework to organize this volume on *Learning, Cognition, and Human Development*, we spent considerable time identifying, discussing, and debating potential topics from both established and emerging areas of research. We made a deliberate decision to reflect contemporary movements in the field and to ensure as broad as possible a representation of topics and scholars. Within each of our five sections, we endeavored to secure, as the first chapter in the line-up, an overview that would serve as an introduction to the area. At the time of planning, we were not sure whether and how the overview chapters would serve our intentions and, indeed, whether it would even be possible to find someone to author these chapters.

The scholars we approached for the overviews exceeded our expectations. Their chapters serve to identify recent debates and developments within which the other chapters in the section are located. In this introduction, we highlight the contribution of the overview chapters in each section and draw connections between them and the respective constituent chapters. We conclude by reflecting on the content in relation to that of the previous edition and by considering ongoing research in the area, looking back and looking forward.

Perspective on Learning: Theory and Methods

Overview chapters at times challenge the reader, and the one leading the perspectives on learning section, by Danish, challenges us to think critically about the key theories of learning studied in the fields of learning, cognition, and human development, and particularly about the importance of recognizing the contexts within which these theories have been developed and are used. Emphasizing that theories of learning are situated in time and place, Danish initiates a conversation about how theories describe learning in the world that we live in now and in the wide range of learning contexts that reflect where learners are, including both formal and informal contexts. Acknowledging that this makes the conversation about what learning is more complicated, the author also notes that it increases the chance that we can engage in conversations about how these theories describe, and consequently shape, learning in the world and not simply function to prompt conversations between scholars. The title of the chapter encourages readers to ask of each theory "for whom?" and "to what end?" and discusses what our theories of learning do not yet address, in the hope of pushing us all to think more deeply about what theories of learning can and should do in the future.

Authors of the chapters in this section have a view about "to what end" the perspective they take is intended to function with respect to furthering the field of learning. The chapter on social cognitive theory emphasizes the theory's reflection of reciprocal interactions between personal, behavioral, and social/environmental variables, while that concerned with theories of embodied cognition discusses how concepts are essentially constituted by reinstatements of experiences related to perception and introspection as well as to bodily actions. The chapter offering a sociocultural perspective is clear about the role of theory in conceptualizing learning and development in the complex world that we live in. However, it is the author of the chapter on learning from a behaviorist perspective who asserts, perhaps controversially, that a science of practical use will be behavioristic in perspective. This section also reaches beyond more traditional theoretical perspectives to present a chapter considering the contribution of the interdisciplinary learning sciences perspective not only to advancing theoretical conceptions of learning but also to the act of

supporting learning, including new methodological approaches. Another interdisciplinary approach, as a response to complexity, is the chapter on educational neuroscience which illustrates how combining perspectives from psychology, neuroscience, and genetics helps to unravel mechanisms underlying learning. Further to the notion of the overview chapter that theories and perspectives are situated in time and place, there are two chapters relating to contemporary phenomena: one examines learning analytics, a recent interdisciplinary field encompassing learning (e.g., learning sciences), analytics (e.g., data science), and human-centered design perspectives, and the other discusses the perspectives of artificial intelligence and machine learning as they relate to education.

The Learner: Fundamental Processes

Reading Wiley and Guerrero's overview of fundamental processes of learning, one might be forgiven for thinking of it as an overview of the entire volume. Its coverage is both broad and deep. Consistent with the title, they adopt a largely cognitive perspective on many aspects of mental functioning: memory, attention, comprehension, reasoning, knowledge, and the like. They situate memory at the center of all cognitive processes and as fundamental for learning, but also give due consideration to comprehension and other higher-order cognitive processes. Comprehension, of course, fundamentally depends on memory but active engagement with the information is essential if the learner is to construct a rich mental representation. Under the heading of memory, comprehension, and other processes, they systematically consider conditions that may improve these processes and here they employ both cognitive and sociocultural theories of learning, touching on the importance of interaction with others be they peers or more knowledgeable others. They also consider skill acquisition over time, in reading and math, and in first- and second-language acquisition. The now taken-as-given mantra from constructivist theory of the learner as an active agent in their own learning is alive and well in Wiley and Guerrero's overview.

Other chapters in this section pick up on the cognitive perspective with due consideration given to attentional processes, processing limitations, expertise, knowledge, problem-solving, reasoning, and, of course, memory. But where these other chapters extend beyond the overview provided by Wiley and Guerrero is in consideration of more affective and social processes and constructs. Here we see discussion of creativity, curiosity and interest, emotion, grit and resilience, as well as self-concept and self-efficacy. The learner might indeed be an active agent in their own learning, and deploy various cognitive resources and processes as demanded by the task, but key affective and social influences support these cognitive resources and processes and, in turn, are fueled by these resources and processes. Learning is indeed much more than a cognitive endeavor.

Learning in Contexts and Cultures

The overview chapter that leads the contexts and cultures section, by Cope, Kalantzis and Tzirdes, provides one set of lenses to consider the conceptual underpinnings of this section. The first lens is the general distinction between learning that happens in the informal context of the lifeworld, contrasted with the formal or institutionalized learning of programs, curricula and syllabi—called “education.” The second lens is the social functions of both informal and formal learning, focusing on the role of education for working life, personal life, and public life. Then, cross-cutting these contexts, the authors discuss the increasing significance today of social diversity and digital tools for meaning-making. The overview finally moves from education to the broader society within which it functions to address the question, how and in what ways can learning be a force for educational justice and social change?

The other chapters in the section reflect, and refocus, some of these lenses. The two chapters that follow the overview broadly relate to the question the authors of the overview pose regarding educational justice and social change. The chapter on cross-cultural perspectives on learning offers an expansive understanding of culture not as static and homogenous, but rather as participation in cultural practices that include homogeneity and heterogeneity within and across time and spaces. Importantly, it provides research-based examples of educational efforts to recruit culturally rooted repertoires of practice to support learning. The chapter on Indigenous student identity development and school success discusses how Indigenous student academic identities are developed, experienced, and expressed, explaining how schools can create environments that enable Indigenous students to succeed alongside other students, and introducing a model that provides a framework for understanding the important conditions that Indigenous students need to succeed and thrive at school. In consideration of the importance of social context, a chapter considers social relationships at school, and another presents a social and cultural constructivist perspective on learning “problems.”

Then there is a grouping, beginning with a chapter discussing learning in the disciplines, clearly connected to the first lens the overview authors offer, namely, core curriculum learning (in history and social studies, math, reading and writing, the sciences) in formal settings. This group also contains chapters concerning phenomenon like learning an additional language and learning from multiple texts, both significant in our globalized, information-rich context. The second lens, informal learning, is represented through chapters on learning out of school and learning through work. Encompassing the formal, the informal, and the cultural contexts is a chapter which explores the intersection between spaces, materials, culture, and learning, while problematizing the need to look at past and present when designing for learning. It discusses materiality within the context of a Māori marae and within contemporary spaces for learning. Digital tools and contexts, the other phenomenon identified as “cross-cutting” contexts by the overview chapter authors, are well represented in chapters on networked learning, online learning, and social media.

Learning Over Time

In the overview chapter in our Time section, titled *Learning Across the Lifespan*, Alexander and Fusenig argue that much of learning that transpires in the domains and disciplines that form the backbone of formal educational systems is inextricably intertwined with cognition and development. The authors identify and discuss relevant issues pertaining to learning across the lifespan: that there are general principles about the nature of learning, common to diverse theories; that there are contrasting views of the relation between learning and development; that the notions of lifespan and lifelong learning converge on certain premises and practices while diverging on others; and that it is feasible to construct a model that brings together learning and development across the lifespan.

The other chapters in this section mostly concern age groupings commonly identified in educational literature. Integrative approaches characterize the descriptions, for example, efforts to clarify how distinct mechanisms work together to provide a comprehensive, parsimonious, description of infants' learning. In early childhood education, sociocultural theories are seen as significant, drawing attention to the cultural nature of learning and development, the diverse social and cultural contexts for learning and participation, the meaning of play, the cultural-historical significance of tools and materials, and children's agency and capabilities. In accord with the emphases on learning across the lifespan, chapters focus on examining the phenomena of lifelong learning as well as honing in on what characterizes learning, cognition, and development in certain periods in the lifespan. On the topic of neurocognitive aging, we have an interesting chapter on the relationship between educational level and cognitive functioning in aging. Chapters exploring learning progressions and the multiple and multidimensional nature of educational and life transitions conclude this section.

Optimizing Learning

In planning this section, we envisioned descriptions of research-based interventions and pedagogies that have been shown to be effective in promoting student learning, at least in relatively controlled situations—"what works" if you will. In the overview to this section, McNaughton problematizes such a notion. As is evident in the chapters in this section, we have good descriptions of various interventions and pedagogies for promoting learning and, in many cases, good theoretical explanations for their effects. However, scaling up such approaches—giving them wider application beyond the conditions under which they were studied—often presents problems. As McNaughton points out, the assumption in many instances is that, with good descriptions and "robust explanations," we have all that is needed to optimize learning. McNaughton rejects the idea of "what works" in a universal sense and acknowledges the contextual conditions and variations that lead to much variability in learning outcomes. Invoking implementation science (Bryk et al., 2015), he points out that, rather than asking "What works?," a better question is "What works for whom, under what contexts and conditions, and in a way that is sustainable/at scale?" Adopting a systems perspective, McNaughton interrogates the reasons for, sometimes extreme, variability in outcomes and offers suggestions for making progress in optimizing learning. Again from a systems perspective, he posits that differential targeting of interventions for children at risk and from marginalized communities, an emphasis on 21st century skills (inter- and intrapersonal skills, critical thinking, and critical literacy), and preserving identity, language, and culture may serve as potential "solutions" to the optimization dilemma.

One might expect some tension between the challenges posed by McNaughton and the content of the chapters that follow. True to form, they provide rich descriptions of interventions and pedagogies known to enhance learning along with theoretical explanations for their effects. Nonetheless, a close reading reveals that many attempt to address the (boundary) conditions for successful application of a particular pedagogical approach (e.g., inquiry-based learning). We also see attention to how instruction should be differentiated to (optimally) meet the needs of individual students. Issues of equity and diversity come to the fore in many of the chapters, as do the role of digital technologies to promote cooperation and collaboration for learning and development of higher-order thinking skills. In concert with developments in promoting mindfulness and wellbeing, it is here we see efforts to focus on so-called 21st century skills, both cognitive and noncognitive, and attention to learning in both formal and informal contexts. The challenges of scaling up and giving interventions more applicability is a theme in many of the chapters.

Reflections on the Content: Looking Back, Looking Forward

The context in which this Encyclopaedia has been produced is unparalleled. As a result of disruptions accompanying the COVID-19 pandemic, some authors we approached for this volume were unable to commit and some, in the end, were unable to produce their agreed chapters. So there are inevitable gaps. We would like to have included, for example, chapters on learning from a cognitive constructivist perspective, learning difficulties, motivation, self-regulation, 21st century skills, learning and development in middle childhood, and scaffolding and the gradual release of responsibility. Nonetheless, the vast majority of scholars we approached graciously accepted our invitation. We appreciate how fortunate we were to have had the opportunity to read, and learn from, the perspectives of the expert scholars who have written chapters for this volume.

If the previous edition of the *IEE* (2010) can be used as a benchmark, the fields of learning, cognition, and human development have greatly expanded. We were fortunate to secure many more chapters than in the earlier edition. In this volume, in the perspectives on learning section, a wider range of theoretical views on learning is presented. New topics to this edition include the learning sciences, embodied cognition, social and emotional learning, learning analytics, and machine learning. The section on the learner also shows expansion. Here new chapters cover the topics of knowledge, epistemic cognition, cognitive load, executive function, curiosity and interest, self-efficacy, grit and resilience, academic self-concept, and emotion. The factors and conditions considered

in the contexts and cultures section reflect the emphasis on culture and learning as well as the influence of the digital age with chapters on online learning, social media and learning, and learning spaces. Indeed, the influence and reach of ideas from sociocultural theories, in what has traditionally been a field dominated by cognitive perspectives, is apparent throughout this volume, as is the influence of technology. The section on learning over time and in different age groupings is entirely new to this edition, as is the final section on optimizing learning (of course, some topics within these sections received treatment in the previous edition).

As editors, a foremost aim for us was to secure expertise from a broad scholarly community—authors who would likely present a diversity of perspectives to reflect the globalization of our research world. Again in comparison to the previous volume, the number of countries represented by the authors in this volume has grown from 11 to 17 (though the United States still accounts for the largest percentage, one comparable to the last volume). We note that many more scholars from the European continent are now included.

We began this introduction with reference to *How People Learn II* as a framing device to guide the design and assembly of this volume. In that report, the committee identified two broad areas for a future research agenda. One was seeking a better understanding of variability in learning “by connecting research on internal mechanisms of learning with the shaping forces of contextual variation, including culture, social context, instruction, and time of life” (p. 227). The other was advancing understanding of the affordances (and constraints) of digital technologies for learning and ensuring design and developments in this area are well informed by the science of learning. We would like to think, and suggest, that chapters in this volume demonstrate movement in this agenda and that the work described herein goes some way towards realizing these goals.

Introduction

Writing this chapter in 2021, in the United States of America, it is hard not to reflect on what a complicated and messy world we live in. The world continues to struggle with COVID-19, political and social unrest including rampant racism, xenophobia, sexism, and other forms of discrimination, climate change, and uncertain economies, all at a time when technological innovations are increasing at a breakneck pace that has pundits both enthusiastic and frightened. Our personal histories with these different forces shape who we are, and how we understand and navigate the tensions that arise in our lives. All of these issues and opportunities have an undeniable impact upon learners of all ages, and thus on what it means to study learning. Recognizing these contextual issues, we believe that it is important when introducing the section of this volume that focuses on learning theories to situate those theories of learning in this time and place and try to begin a conversation about how they describe learning in the world that we live in now and in the wide range of learning contexts that reflect where learners are, including both formal and informal contexts. Thinking about all of this makes the conversation about what learning is quite a bit more complicated, but it also increases the chance that we can engage in conversations about how these theories describe, and consequently shape, learning in the world and not just within conversations between scholars.

In situating these theories in the current time and place, our intention is to attend to how they reflect, shape, and can support learning in the real world. We see this effort as grounded both in the present and the future that is informed and potentially transformed by our current efforts. That is, we want explicitly to recognize that teachers, learners, and theories of learning are all historical actors (Gutiérrez, 2018), meaning that they are shaped by their past and present contexts, while also having the potential to shape those contexts. Furthermore, the authors of these theories naturally bring their own histories and experiences with them to the act of generating and refining theories, and it is well documented that the academy is not as diverse as the populations that it often studies. The combination of these influences will, in turn, inform how theories continue to grow and evolve in the future. For example, theories that defined local funds of knowledge (Moll et al., 1992) or funds of identity (Esteban-Guitart and Moll, 2014) as resources that can be the basis of learning emerged in response to deficit-oriented approaches to learning that positioned minoritized learners as lacking key experiences or capabilities. Fortunately, the presence of these new theories brings attention to the resources that historically minoritized learners bring with them and have helped shape a whole new generation of theories and theorists (Esteban-Guitart, 2021).

Therefore, we recognize that learning contexts and learning theories are neither neutral, nor ahistorical. Rather, by characterizing how learning occurs, what counts as learning, and when, theories necessarily privilege certain visions of what it means to learn, or to be knowledgeable and capable, and who can do it well. These theories are grounded in and shaped by many forces and systems of power including the theories that came before them, which theories and whose voices get privileged in the field, the structures of the academy, the funding agencies that support research, the politics of local educational institutions, the politics of the nation states where education happens, and the ways they define their borders and those who cross those borders. Obviously, it's not possible for a single chapter to capture all of these important influences. Thus, our goal in this introductory chapter

is to encourage readers to reflect on these social and historical forces as they think about the learning theories that we introduce. We want to help readers to explore not only the basic tenets of these theories but to explicitly highlight and draw attention to how these different forces shaped the theories of learning, and impact the ways they describe learning and learners. In particular, we want to call attention to the idea that the key theories of learning that we study as a field differ not only in how they describe learning, but also in what they make salient and what they miss, or even hide, and the implications that these shifts in focus have for learners as people, and for learning as a lived, historically situated process. In making these differences visible, we encourage readers to interrogate these theories in an effort to think about how theories of learning can be complicit in defining and reifying the challenges that learners face, and also how theories of learning can support a more equitable, just, and positive future. Thus, we are both critical and optimistic in that we believe that theories, including our own, have not yet lived up to their potential to support all learners, but also that calling attention to this can help us move forward as a field to support more diverse learners in a broader range of contexts.

With these tensions and challenges in mind, we also note that the broad range of learning theories have already been reviewed in prior texts and chapters (e.g., [Greeno, 1998](#)) including some of our own work (e.g., [Danish and Gresalfi, 2018](#); [Ma et al., 2020](#)). Much of that work follows what has become a conventional chronological (based on Western scholarship) lens and sequence, building up from behaviorist accounts to cognitive and then ending with sociocultural theories. However, we fear that this common approach hides many of the challenges and motivations that lie within these theories, and also privileges certain theoretical traditions within the academy. For example, cognitive theory, with its focus on the individual, is often positioned in a privileged and central manner, as having overcome the challenges of behaviorism and served as a foundation for sociocultural theories which then get presented as having an additional focus on context and community. Many overview chapters are organized around cognitive notions of what it means to know, to represent knowledge, and to transfer knowledge despite the fact that sociocultural theories challenge the very notion of transfer (e.g., [Beach, 1999](#)), and the importance of seeing how knowledge is represented rather than how knowledge is used (e.g., [Lave, 1982](#)). Thus, while we agree that cognitive theories have much to offer, we also believe that this positioning means that cognitive theories are viewed in a simplistic light, and sociocultural theories are then viewed as an additional “layer” that can be tacked on to cognitive theory, helping to explore the role of the community and context in learning. This does a disservice to both theoretical traditions, ignoring how cognitive theories do position social contexts, and how sociocultural theories begin with fundamentally different assumptions about what it means for individuals, or groups of people to learn. We believe both of these theories have a lot to say about individuals, about social contexts, and about how each can be important for understanding learners and learning, and yet some of those ideas are lost in many of the traditionally organized discussions.

Our intention, therefore, is that this introductory chapter will help to disrupt these norms and challenge the community to reflect on why we typically review the literature in those ways, what that view hides, and what it reveals. We aim to shake things up a little and offer an alternative perspective to help us all think differently about our own theories and those of our colleagues as we look toward the future and reflect on what theory might do, and might become. We therefore present sociocultural theories first, followed by cognitive theories. We are also inspired by the work of [Philip et al. \(2018\)](#), to ask the following questions to help situate each of the theoretical traditions we will review: **How does this theory address learning, for whom, and to what end?** The intention of these questions is to recognize explicitly the way in which each theory and its chosen focus necessarily illuminates certain learning phenomena and simultaneously hides others. This necessarily shapes whose experiences, opportunities, and struggles might be highlighted or impacted by the theories, as well as the outcomes that the theories define and support as valuable. Using this lens helps us focus on how each theory may impact learners and learning within our societies. It is important to note that in attempting to answer this, we are necessarily offering our perspective on who is supported by any given analysis or study, and the goals of those studies. This will naturally reveal our own theoretical biases regarding the impact these theories have had. Whether a specific intervention does or does not actually feel inclusive to a given person or group of people is an empirical question that we might answer in the future. Answering the question “to what end” is even more potentially controversial as not all authors address this concern. Again, therefore, our goal is to present our perspective, and encourage each reader to develop their own. After discussing “for whom” and “to what end,” we highlight a few new directions that we believe have emerged in each tradition that we believe will be part of defining future scholarship.

Our positionality

Before we articulate our views of the key learning theory traditions, we believe it is important to note who we are as that shapes our approach to this exercise. We both consider ourselves “Learning Scientists” who have elements of “traditional” training in learning theories (e.g., the first author has a Ph.D. in Educational Psychology). However, we would both label ourselves as primarily sociocultural theorists. We are also deeply interested in pursuing issues of equity and justice through the study of learning. We also identify as theory builders and educators who seek to expand and transform the possibilities for how these theories of learning are understood. That is, like all authors, we have our biases. At the same time, our intent is not to label a single “correct” or objectively “better” theory because we do not believe that such a thing exists. Rather, we suggest that each theory is better for different people, goals, contexts, and tasks, and that these theories also have the potential to cause harm both directly and indirectly. We want to help all readers of learning theories to reflect on that, and on their own values as they consider learning.

Learning in context (sociocultural theories of learning)

Among the many flavors of sociocultural theories of learning, the commonality between them is that context is inextricably embedded in accounts of how people learn in messy real-world situations. However, the definition of context is defined in a range of ways, as is the relationship between context and learning—both of which, in turn, shape how learning is defined. One commonality, however, is that culture is considered a key element of context. Furthermore, as Lee et al. (2020) noted, “it is not simply that culture *impacts* development, but that development itself is cultural in nature” (p. xxii). For example, cultural historical activity theory (CHAT), which itself has many flavors, builds from Vygotsky (1978) and others’ arguments (e.g., Leontiev, 1978; Luria, 1976) that all cognition and therefore learning is shaped by the context of human activity, and the cultural tools that mediate all such activity (Cole and Engeström, 2007). Mediation refers to the ways that cultural tools can transform our perception of, and relationships with, people, tools, and goals, and all mediators are both material and semiotic, reflecting the fact that they have a physical impact on the world as well as a social one (Wertsch, 1981; 2017). Within a CHAT account, learning depends on changing interactions between people and tools (the mediators), developed over time by cultural communities, and these interactions in turn shape and potentially change those cultural communities. To understand how learning happens within these interactions, the key unit of analysis for CHAT is the activity system, which is defined by a shared object or set of goals that a community of people pursues together. To understand learning, we need to be able to see how relationships and tools are taken up in new ways through meaningful human activity (e.g., a shift in mediational means).

While some count only those accounts of learning based on activity theory in the category of sociocultural, we include all theories that take learning and development to be interdependent with socially and culturally constructed context. Legitimate peripheral participation (LPP; Lave and Wenger, 1991), for example, developed through a framework of social practice theory, treats learning as shifts in participation in activity. The focus for LPP is on what learners *do* in the context of activity, or how their practices change, rather than what they *know* (or come to know). To many, LPP and CHAT sound quite similar, though Sfard (1998) characterized the important difference between theories that use the metaphor of acquisition of knowledge to describe learning (e.g., the internalization or appropriation of mediational tools that Vygotsky referred to), and theories that instead use the metaphor of participation (e.g., the changing participation that Lave and Wenger referred to). Some sociocultural theorists bridge this divide by incorporating elements of both acquisition and participation metaphors in their accounts.

Others have also noted that the nuanced differences between these theories have implications for how educators may design learning experiences (Engeström, 1991). For example, a social practice theory like LPP invites analysis to foreground not just how individuals change as they participate in the ongoing work of their communities, but also attend to how the practices themselves are constituted through “situated negotiation and renegotiation of meaning in the world” (Lave and Wenger, 1991, p. 51). A Vygotskian (1978) lens, on the other hand, may focus on how individuals appropriate the use of individual mediational means. In contrast, more recent CHAT work appears to incorporate elements of both by focusing on how individuals are shaped by mediational means, but also how they participate in mediational actions in new ways that in turn can transform the activity system (Engeström, 2018).

Despite these differences, it becomes clear that sociocultural lenses view activity and social practice as more than simply a context *for* learning, but instead part and parcel *of* learning, and vice versa. In fact, many who use these theories understand “knowledge” as only taking on meaning *in use*, rather than a static system of skills and concepts acquired and carried around by learners. Therefore, learning is assumed to be *always* occurring, despite educators’ anxieties that their students are not learning and policy-makers’ war against “learning loss” (McKinney de Royston and Vossoughi, 2021). In other words, rather than *whether* something was learned or not, the questions that these theories help us ask are about *what was learned*, given the particularities of any given context.

For whom?

In order to discuss who learns in sociocultural studies of learning, it is valuable first to understand how sociocultural theories characterize identity. Sociocultural lenses treat identity as an integral part of learning. LPP, for example, is explicit that learning “implies becoming a full participant, a member, a kind of person” (Lave and Wenger, 1991, p. 53). Therefore, the study of an individual’s learning is incomplete without taking into account their shifting identities in relation to the learning of interest. While different ways of theorizing identity have been developed (e.g., Holland et al., 1998; Nasir, 2002; Stetsenko, 2009; Wenger, 1998), those that are compatible with (and build upon) sociocultural theories understand that identities are multiple, relational, formed and negotiated in context and in interaction, and shape learning even as they themselves develop (Philip and Gupta, 2020). This complicates any attempt to answer, “For whom?” because it challenges the very notion of categorizing people.

Furthermore, given how identities are implicated in sociocultural theories of learning, who learners are (or can be) must be investigated in relation to their contexts. Gee (1989) gave the example that it would not be very sensible to ask if the Pope was a bachelor, given his vow to remain unmarried. Similarly, in tracked schools it might make sense to discuss students as “fast” or “slow,” as the teachers in Horn (2007) did, whereas in an untracked school, where all students are assumed to be capable of success and rate of learning is less emphasized, these categories may be irrelevant. Additionally, theoretical lenses shape the possibilities for how analysts see different kinds of actors. Sociocultural theories illuminate not just the developing identities of learners, but also the social, cultural, and historical contexts that allow for and support or suppress particular kinds of identities. This stance makes it imperative to study diverse learners in the diverse contexts in which they live. For this reason, many scholars interested in supporting historically minoritized learners have chosen sociocultural theories as their underlying framework.

A number of theories have emerged from a sociocultural framework that focus on the challenges that arise for learners from non-dominant communities, particularly when the cultural history that they bring with them is not valued by the dominant culture of their school, context, or society (Moll et al., 1992). For example, Funds of Identity theory builds on Funds of Knowledge (FoK) and other sociocultural theories to highlight how individual learners are each unique and may connect to or find relevance in different aspects of their cultural identities, which can in turn serve as resource for their learning (Esteban-Guitart, 2021; Esteban-Guitart and Moll, 2014). Culturally responsive pedagogy inspired theories (Ladson-Billings, 2014) build on the idea that learners bring valuable cultural resources with them to formal learning contexts, and further note the importance of helping learners take a critical lens to their schooling so that they can appreciate and navigate the challenges that formal schooling often has for minoritized learners. Culturally sustaining theories go even further to promote recognizing, supporting, and lifting up learners' home cultural knowledge, explicitly arguing against assimilation as a goal of schooling (Paris and Alim, 2014). In short, while sociocultural theory does not require a focus on historically minoritized learners, it has proven a powerful tool for researchers to articulate and examine how learners' identities may conflict with those of the dominant cultural groups in a given context, and has begun to provide insights into how the field can support more diverse learners in these circumstances.

To what end?

As mentioned above, sociocultural theories have illuminated schools and classrooms as cultural communities in and of themselves. These studies have often been conducted with a goal of supporting all learners in being successful, though scholars have noted that this may require schools and other institutional factors to be fundamentally transformed (Sengupta-Irving, 2021). Sociocultural theories have proven useful tools for better understanding schooling as laden with cultural norms and practices that, at best, are a mismatch for some communities of learners, and, at worst, systematically marginalize and otherwise harm them (Nasir et al., 2008). In fact, some have gone further to point out how school-based learning is a relatively recent invention, and often at-odds with developing robust understanding of how to participate in society (e.g., Vakil, 2018). A result of these efforts is that the field has also taken up sociocultural theories to understand that schools are not the only place valuable learning happens; decentering schools has the potential to also decenter the dominant values and practices embedded there and, consequently, acknowledge and lift up others that have historically been erased. That is, many sociocultural studies of learning have an explicit goal of rethinking what education looks like, and for whom.

In addition to studying schooling, sociocultural theories have been taken up to study disciplinary practices, including mathematics, science, and literacies, in family, community, and workplace contexts (e.g., Booker and Goldman, 2016; Hall and Jurow, 2015), and how the organization of those contexts shapes disciplinary practices. This has served two important purposes. First, these studies have provided new ways for thinking about formal schooling, and how it might be reimagined to support learning of disciplinary norms. Second, however, these studies have shown how important it is to examine learning in non-schooling contexts as an important space for helping all learners to be successful in appropriating disciplinary expertise of value to them (Jackson, 2011).

Related approaches

In this section we briefly address some of the many promising approaches that have grown from sociocultural theory and gained momentum in the past decade. One long-standing concern of sociocultural theorists involves the many communities or activity systems of which a learner is a part. One way to take these into consideration is what has been called "third generation CHAT", where multiple intersecting activity systems constitute contexts for learning (Engeström, 2018). This notion has been addressed in a variety of additional ways, from Vossoughi and Gutiérrez (2014) arguing for multi-sited orientations to Barron's (2006) learning ecologies framework and Bell et al.'s (2021) cultural learning pathways. There are nuances differentiating these ideas, but crucial for all of them is the assembling of multiple contexts that learners navigate. This has had the general effect of bringing various contexts previously thought incompatible with, or irrelevant to, each other into analytic relationship, demonstrating how home and community practices can support school learning (e.g., Civil, 2002; Lee, 2001), or how the views of students constructed by processes of schooling can be narrow and harmful (e.g., Jackson, 2011). Further, better understanding of the various contexts of learners' activity is critical for researchers and educators to move beyond deficit views of marginalized communities and learn about and how to value their diverse practices and ways of knowing (Nasir et al., 2008). An important dimension of this work is that it also frequently treats the content or community as a learner, recognizing that clubs, schools, workplaces, and communities can all learn and grow (Cole and Engeström, 1993; Engeström, 1991, 2018). Furthermore, these communities grow in a dialectical relationship between the individual and the community, with individuals helping to transform the community, while also taking on new community practices. This fundamentally shifts the answer to "for whom?" to include groups of people in new and powerful ways.

Sociocultural theorists have also begun to consider more expansive notions of what constitutes a context for learning. For example, some theories of embodied cognition and embodiment consider learning to be located in the whole body, or multiple bodies in interaction, rather than simply the individual mind or brain, thereby implicating the body as both a cultural artifact that mediates learning as well as the learning subject, while continuing to highlight the role of social context and interaction in mediating this process (e.g., Danish et al., 2020; Gholson and Martin, 2019; Hall and Nemirovsky, 2012; Kelton and Ma, 2018; Takeuchi and Ishihara, 2020). Another aspect of context made increasingly relevant is spatiality, beyond space as static containers for activity (Leander et al., 2010). How spaces are constructed, oriented to, moved through, and understood as social sites of activity

and power have crucial consequences for what kinds of learning are made available, and for whom (e.g., [Marin, 2020](#); [Rahm, 2014](#); [Taylor, 2020](#)). Finally, we note the importance of phenomena that have begun to be investigated simultaneously as targets for learning as well as context for learning, such as emotion ([Vea, 2020](#)), dignity ([Espinoza et al., 2020](#)), ideology ([Philip et al., 2018a,b](#)), and axiological positionings ([Bang et al., 2016](#)). These bring an explicitly ethical dimension to our theories of learning, which we argue is urgently important in an effort for education research to work toward justice.

Individual learning (cognitive theories of learning)

There are many theories that fit under the “cognitive” umbrella including cognitive science, social cognitive theory, sociocognitive theory, constructivist theory, and information processing theories, but what they share in common is a fundamental focus on how thinking and learning of individuals can be modeled and understood in individual minds, with work in neuroscience going one step further to explore how knowledge is represented within the brain itself. By modeling these processes it becomes possible not only to understand them, but to support them more effectively. The majority of these approaches also build on computers and computational techniques as a sometimes implicit, underlying metaphor for how the mind and brain work, and many trace the early rise of cognitive science to the parallel rise in computing and computer science ([Block, 1990](#)). Building on the metaphor of the computer, many cognitive approaches focus on how information is processed, and stored in or retrieved from memory ([Bransford et al., 2000](#)). While more recent work does not always explicitly mention the computer as an inspiration, the focus on modeling how thinking, learning, memory, and perception are all related in one system is quite common. In part due to efforts to model cognition in this way, and in part due to a long tradition in psychology and related fields that have focused on individuals, cognitive approaches to thinking and learning typically privilege the individual person as the primary unit of analysis. Cognitive theorists then explore how information is perceived by the individual, represented in their mind and, ultimately, transformed or processed to support the kinds of activities that scholars are interested in.

Despite these similarities, cognitive theories focus on a broad range of phenomena, at grain sizes ranging from the process by which ideas are captured in our neurons to how we solve problems in complex tasks. For example, constructivists, building on the tradition of Piaget, tend to focus on the various kinds of information that individuals process (e.g., whether concrete or abstract), and document how this changes as children develop, with a particular focus on how it influences their performance on specific tasks ([Ginsburg and Oppen, 1988](#)). In contrast, cognitive scientists typically focus more explicitly on how important concepts are perceived and represented, while social constructivists explore the role of other people in one’s life in shaping one’s cognition ([Danish and Gresalfi, 2018](#)). Related theories such as theories of motivation can then build on this framework by exploring how cognitive processing is shaped by related variables including how learners value the content they are studying, and whether they believe that they can learn it—with research indicating that learners are more likely to persist in situations that they value and where they expect a reasonable chance at success ([Hidi and Harackiewicz, 2000](#)). Theories of meta-cognition also extend the focus of cognitive processing to consider how learners reflect on cognition itself, and how this can lead to strategies for improving one’s own learning and memory ([Finley et al., 2010](#)).

In contrasting cognitive theories with sociocultural theories, it is important to note that cognitive theorists do not deny the fundamental importance of culture and context. Rather, they view these as variables that might be modeled along with other important factors and viewed within the same fundamental model of cognition. After all, a key concept in cognitive theories of learning is how prior knowledge shapes one’s experiences of new situations, and how one connects new knowledge to existing structures ([Bransford et al., 2000](#)). From this perspective, experiences that are tied to the social world are modeled as aspects of perception, prior knowledge, and knowledge construction. For example, schema theory has long focused on how individuals remember, understand, and engage with cultural norms or scripts ([Rumelhart, 1980](#)). This difference in how the theories explore social interactions has led to a fundamental tension between theoretical frameworks, with cognitive theorists noting that many sociocultural frameworks are too vague in how they describe knowledge and knowledge construction because they do not explicitly model those interactions, while sociocultural scholars push back noting that treating context and culture as a variable diminishes their importance and allows one to treat thinking and learning as separable from context in ways that sociocultural theorists believe are inherently problematic. Some of these disagreements can be best seen in a now famous debate between [Anderson et al. \(1996\)](#), representing individual approaches, and [Greeno \(1997\)](#) representing sociocultural ones. This tension has led to some efforts to reconcile the disparate theoretical frameworks by viewing cognition as situated within sociocultural contexts, and by attempting to synthesize across them ([Danish and Gresalfi, 2018](#); [Sfard, 1998](#)). For example, the cognitive apprenticeship model explores how social relations of apprenticeship can support and help develop cognitive processes ([Collins et al., 1988](#)).

For whom?

Cognitive theories have historically been at the forefront of identifying how learners can engage with the kinds of content that have long been privileged in schools, helping to identify how learners come to be able to read and write, engage with mathematics, explore scientific concepts, and understand historical accounts ([Bransford et al., 2000](#)). Cognitive theories are particularly well-suited for the focus that is common in Western schooling traditions on understanding how individual students struggle, or excel when engaging with these core, disciplinary ideas as presented by schools. To accomplish this, cognitive theorists typically identify

a normative vision of what is valued as important for success within a discipline, often identified by disciplinary experts (Herrenkohl and Polman, 2018). They then model how individuals do or do not live up to that model. This can be quite powerful because it provides insights into the underlying mechanisms of learning, and thus provides clear suggestions for what might lead some learners to struggle. However, this approach also naturally centers those who are pursuing and/or interested in following these normative trajectories, with less attention to those who aim to resist or pursue alternative goals.

Nonetheless, within the bounds of school-based learning, cognitive approaches have proven useful in supporting both those who are traditionally successful, and those who struggle. For those who are traditionally successful in school, cognitive accounts provide both an explanation, and an opportunity to excel. In contrast, for those who struggle, cognitive accounts have proven crucial in helping identify underlying causes for perceived failure. For example, research that focuses on the relationship between metacognition and self-regulation has noted that successful learners are able to track their progress as they learn new content and challenge themselves to persevere in working with challenging ideas. Unsuccessful students struggle with this, but a wide range of scaffolds have been designed which can help learners to regulate their learning experience and know when it is best to revisit an idea or move on to a new one (Prather et al., 2020).

To what end?

The majority of the individual-focused, cognitive work we are most familiar with is aimed at achieving one of two ends, and often, but not always, both: (1) developing a more robust account of cognition and learning as a form of basic science from which more applied approaches can build, or (2) focusing on the applied dimension by improving practice that relies on cognition, for which education is but one practice, with others including professions, decision making, and building computer systems, to name a few. The first focus aligns well with the tendency of many cognitive studies to employ laboratory-based, experimental studies in that it is possible to build a robust and nuanced model of learning in those environments, without the kinds of complications and confounds that make some implementation-oriented studies challenging. In contrast, studies that share this second focus on improving practice must address many of these issues, though they often aim to do so by developing generalizable claims that cut across contexts and contextual variables because of the underlying assumption that minds operate in similar ways, and thus differences in how individuals act can be attributed to observable differences in their experiences, the context, or both.

In the first category, a key outcome of this effort is that cognitive models tend to be detailed and precise, and to predict outcomes in controlled environments. This focus on predictability and explainability is a hallmark of this approach and provides designers and researchers with clear empirically-testable design choices. For example, Mayer's theory of multimedia learning (Mayer, 2019) has evolved to include an explicit list of principles that can be employed when developing multimedia content to be viewed by individual learners. This includes the multimedia principle, which notes that the simple inclusion of pictures with words can help learners to develop a more elaborate understanding when the pictures add information that expands on and clarifies the words (redundant information is less productive).

If we look deeper into the second category that focuses on informing and improving practices including those in schools, it is important to ask what kinds of learning, or subjects are typically a focus? Here we see a distinct focus on disciplinary content that aligns with the current structure of school systems. For example, in their introduction to the Handbook of Research on Learning and Instruction, Mayer and Alexander (2010) note "The psychology of subject matter is the scientific study of how people learn school subjects such as reading ... and has been recognized as one of the major accomplishments of educational psychology" (p. 3). They rightly note that studies of these disciplinary areas go back over a century, and are oriented toward long-standing curricular boundaries, often those defined by experts within their field, or as is often the case, at least in part by politicians and political forces that shape many of our national education systems. There is a clear benefit to this in that it focuses attention on helping students to succeed within existing educational structures, with a specific goal of those students being able to perform successfully within those contexts (e.g., pass key tests). Within many societies, this process is also linked quite explicitly to future employability, and thus the goal is to train members of the society for employment within their local context.

Much of this work is also aimed at efficiency—how to support learners most effectively, in accomplishing as much as possible at the lowest possible cost in terms of time, resources, or both. This is certainly a goal that drives much of corporate-backed research. Even in purely academic contexts, however, increasing demands on teacher time, and decreasing budgets in many educational systems necessitate this kind of focus on efficiency. There are also motivational benefits, as students can spend their time engaging in productive learning opportunities rather than dedicating time to ineffective approaches.

Related approaches

While there are too many subfields to list here, a few key areas that have gained increasing attention and which each have their own chapter in this volume are educational explorations of neuroscience, advances in computational modeling of cognition and learning, and embodied cognition.

One prominent trend is attention to how innovations in neuroscience help the field to think more deeply about how cognition works on multiple levels. This is incredibly important given the value of viewing cognition at multiple levels simultaneously, as a way of appreciating if and how each level might be shaped by those which help to define it, or those that it helps to define (Marr, 1982). For example, many cognitive accounts are built on the assumption that cognition is both enabled and constrained

by various forms of memory (long and short term, conceptual or semantic, emotional and conceptual, etc.). Research into neuroscience has provided us with additional detail regarding how those memories are stored, and how they are related to each other in addition to how different parts of the brain contribute to this kind of activity given that findings indicate that the neurological architecture of thinking and learning is distributed (Just and Varma, 2007). This kind of research can provide simultaneously insights into prior observations about how we remember or recall important concepts, as well as the kinds of concepts that might be important to look for in studies of cognition. However, it is important to note that limits in how we can currently examine neurological processing necessarily limit the kinds of studies that can be conducted. For example, many measures such as fMRI rely upon focusing on simple, discrete actions such as decoding a word while remaining still (Gazzaniga et al., 2013), and struggle to document the kinds of long-term, continuous activity common in many classrooms. There is optimism that growth in neuroscience techniques and methods will overcome these challenges, but this necessarily limits the benefits of these findings in the short-term.

Advances in understanding neural architecture, in many cases, have paralleled advances in how we can model thinking and learning in computers. Continuous advances in computational power and tools have also fueled incredible growth in efforts that aim to model cognition and learning using computers. Broadly, these efforts can be divided into two overlapping categories: (1) efforts to reproduce intelligent behavior, and (2) efforts to document and understand cognition and learning. The first category includes efforts to produce Artificial Intelligence—tools that behave in ways that emulate or exceed what humans can do. Our lives are filled with such tools ranging from Apple’s Siri and Amazon’s Alexa to self-driving cars. The second category refers to those efforts to either model how humans are learning, such as cognitive tutors (Koedinger and Corbett, 2006) or pedagogical agents (Schroeder et al., 2013), and those efforts to identify patterns in learning and learning activity, often referred to under the umbrella term “Learning Analytics” (Wise et al., 2014). Naturally, innovations in these two areas often inform one another in powerful, synergistic ways. However, it is important to again note that the nature of these technologies often limits them. For example, many intelligent tutors are focused on math or computer science concepts that are easier to represent in a computer, with less attention to humanities content (for an exception see Easterday et al., 2012). Nonetheless, intelligent tutors have been shown to help thousands of learners to engage with previously challenging concepts (Koedinger and Alevan, 2015). However, it has been well documented how computational technologies, while promising, are not easily adopted and incorporated in all school systems and, in fact, are often adopted first in the privileged school districts that need them least (Apple, 1998). Therefore, we caution readers to examine these technological innovations with an eye toward who is currently benefiting from them, and what implications this might have for the future integration of these tools in schools and informal learning environments?

Embodied cognition is also studied quite heavily in the context of the individual and individual cognition, sometimes along with the neural basis of embodiment. The embodied turn in cognitive theories arose out of recognition that many of the same underlying cognitive/neurological systems that drive perception and action are also implicated in the kinds of reasoning that are often of value to scholars (Lindgren and Johnson-Glenberg, 2013). From this finding emerged recognition that a deeper understanding of this link could help us better understand how certain ideas are engaged, and how they can further be supported by attention to this overlap. For example, Alibali and Nathan (2012) demonstrated the importance of teachers’ gestures for helping learners to understand complex mathematical relationships. A range of theories have arisen that argue for various levels of the link between cognition and the body, some arguing that the body is always involved in cognition and learning, while others instead recognize only some crucial connections with key analogies that are exploited by learners and might be made more salient by educators. As with many other innovations, the focus on embodiment has largely been tied to existing disciplinary concepts that are already well-understood and are based on the kinds of embodiment that are familiar to the majority of learners. Fewer studies have focused on the kinds of concepts that embodiment might open up, that are not previously core to our learning environments. In addition, while the focus on embodiment has undeniable potential, we think it is worth asking what this means for learners who do not want to embody ideas, who have non-normative ways of embodying ideas, or who have specific traumatic experiences with embodiment (Fitzgerald, 2005)? Our hope is that future work in embodied cognition from both the individual and sociocultural perspectives will also incorporate these many learners.

What have we been missing?

As mentioned above, theories of learning are neither ahistorical nor neutral. They develop and get taken up in the context of social, political, and economic agendas (e.g., see Philip and Sengupta, 2020), and necessarily privilege certain viewpoints and background others. In doing so, they illuminate particular aspects of learning phenomena and obscure, or even distort, others. We acknowledge that, even with the best of intentions, in this overview chapter we have taken up and centered those clusters of theories dominant in the learning sciences. We hope that this final section may provide a developmental dimension to our overview—some insight into the field (and the authors of this chapter) as dynamic and itself (and ourselves) learning, with all the possibilities that may hold. Inspired and informed by less-commonly cited as well as more recent scholarship, we make note of what the dominant theories above have neglected, or decentered, or, in some cases, deliberately eradicated, and point to work that promises to shine the light anew on learning phenomena and the communities which steward them.

We begin by making note of two “common sense” (Garfinkel, 1967) assumptions and dimensions of dominant theories of learning to help bring into relief some of what the field has, for the most part, neglected. To begin, it is widely accepted that some activities count as learning, while (most) other activities do not. In fact, it is assumed that learning of value is so difficult

to achieve that most of our educational research, policy, and on-the-ground efforts are directed toward promoting it. However, research that decenters environments designed primarily for learning, like schools, helps us to decouple theories of learning from theories of teaching and thus recognize that important learning happens everywhere, all the time (Lave, 1982). Studies of previously unacknowledged or undervalued learning may contribute transformative dimensions for what matters for learning, or what counts for learning. Headrick Taylor's (2017) work, for example, highlights mobility and spatiality as a previously dismissed dimension of learning by exploring how youth who had access to bicycles began to think of their urban locale in new ways and allowing us to better understand emplacement and place-making as consequential for the health and survival of communities. A focus on mobility and spatiality not only illuminates neglected objects of learning, but also may expand our understandings of what counts as previously taken-for-granted disciplinary learning (e.g., mathematics; Kelton and Ma, 2020). Relatedly, scholarship that interrogates different forms of learning (e.g., Rogoff's work on learning by observing and pitching in, 2014) may contribute to theorizing that brings into relief previously unvalued activity, especially among non-dominant communities, as learning.

Additionally, we tend to see learning as an individual human phenomenon. To focus on individuals means our investigations of cultural and collective learning are limited to how they relate to individual learning, or perhaps how the individual and social are interrelated, but always with the individual at center. However, studies of consequential learning (Jurow et al., 2016) and social movements (Curnow and Jurow, 2021) demonstrate that units of analysis beyond the individual are valuable in their own right, not simply because of their interrelations with individual development. This learning-as-individual-and-human orientation also reproduces human exceptionalism, the idea that humans are fundamentally different from and more important than other forms of life (Bang, 2016). In CHAT, for example, learning is defined through the premise that "material objects are modified by human beings as a means of regulating their interactions with the world and each other" (Cole and Engeström, 2007, p. 485). Our theories of learning are therefore limited to treating the more than human, lands and water, and other phenomena as context for—or objects of—learning, rather than subjects of learning. Bang argued that this constitutes an epistemic erasure of Indigenous ways of knowing, and worse, has served to justify the denial of the most basic of rights to groups like enslaved peoples and communities that have been targets of genocide. In contrast, by recognizing the ways that Indigenous communities view the more-than-human world as part of their own experiences it becomes possible to study new ways of learning when humans explore the natural spaces around them (Marin and Bang, 2018).

For whom and to what end?

The contexts in which theory itself is constructed are inextricably embedded within the theory itself. It is not simply trivia, for example, that Vygotsky's ideas were developed (and then, along with other educational psychology-related work, suppressed) in postrevolutionary Russia (Cole and Scribner, 1978; Kozulin, 1986), or that Lave's situative theories developed in response to worrisome "political and ethical implications of cross-cultural psychological experimentation" (p. 1, Lave, 2011). We highlight this not to suggest that theories cannot be taken up across contexts, but instead to emphasize the importance of historicizing theory as situated tools for meaning-making. This is important for avoiding, for example, naive assumptions about theory as universal or neutral. At the same time, it is equally critical to avoid notions of portability—that Indigenous epistemologies, for example, can or should be used by anyone in any expedient manner. Instead, theory may be read and taken up with a deliberate eye toward voices and values that may be silenced or otherwise marginalized (Gholson, 2019; Philip and Sengupta, 2020), or co-opted (Tuck and Yang, 2012). This is a step toward more deliberately considering for whom we do our theorizing, and to what end.

The power of theory lies in its ability to represent the world and provide a "reality" to its users (Frye, 1983). In providing a reality, however, Frye noted the ease with which entire communities may be rendered non-existent. For theories of learning, this often entails assumptions about what normative learning processes or outcomes look like, with consequences for whom is viewed as able to learn and who is not. As a consequence, in some cases, communities or categories of learners get studied separately (e.g., learners with dis/abilities, emergent bilinguals, or racially marginalized learners). In others, categories become meaningless (e.g., LGBTQI identities are often treated as irrelevant in STEM learning; Velamuri et al., 2021). In some cases, the historical and socio-political contexts of learners necessitate theory that takes these issues into consideration (e.g., Annamma et al., 2013, take up Critical Race Theory in the context of dis/ability studies). We argue, however, that these concerns must not remain the domain of "specialized" sub-disciplines of the learning sciences, but instead constitute the purview of all learning scientists.

Final notes on reading theories of learning

Following Philip and Sengupta, we urge readers of learning theories to read contextually, consequentially, and contrapuntally. They explain:

To read contextually is to account for the political influences and forces, people, and openings that seed designs and theories and allow them to emerge, flourish, or languish. To read consequentially is to consider the possible ramifications of innovations, with an eye toward responsibility (Stilgoe et al., 2013), and with the courage for new social and political imaginations (Cutierrez, 2016). To read contrapuntally, as Said (1993) outlined, means "to draw out, extend, give emphasis and voice to [the logics of and resistances to empire and imperialism that] are silent or marginally present or ideologically represented" (p. 66) in our designs and theories (p. 335).

We add to this call the importance for scholars to read theory reflexively. Lather's (1986) points about reflexivity in terms of research design and methodology are relevant here as well. Our own positions in relation to current political configurations, the learners we study, the institutions in which they are entangled, the institutions in which *we* are entangled, are all implicated in how we read, and subsequently take up theory. In particular, we highlight the idea of reciprocity, reading dialogically to see how theory might help us negotiate meaning and value with the learners we study. In these ways readers of theory may construct what Gholson (2019) called a scholarly catchment, understanding theoretical narratives from multiple perspectives and positions, "flowing like water" (p. 419). In this scholarly catchment lies possible futures our theories of learning may lead us to.

Acknowledgments

We thank members of the Indiana University Representations, Activity, Play and Technology (RAPT) lab and New York University's Interaction, Analysis, and Learning Lab for their feedback on this chapter. We also thank Michael Kieffer for his feedback on several sections of this manuscript.

The beginning

In 1913, John B. Watson (1878–1958) gave voice to a set of ideas that upended the then-dominant approaches in psychology: structuralism and functionalism. Instead of consciousness and introspected mental states, inaccessible to a third party, hence impossible to verify, Watson argued that publicly accessible *behavior* should be the proper datum for psychology. Behavioristic psychology should follow the lead of the “hard” sciences, by sticking to measurable things. It should learn from biology and look to animals as well as humans for its principles.

Watson, like B. F. Skinner after him, intended that behavior should be studied not as a cue to the “mind” or even the nervous system but, “for its own sake.” By *behavior* they meant the activities of the whole organism in context: what it is doing, what the environment in which it acts is, what its history has been, and what the effects of its actions are. To do good science means controlling all these things—history, environment, past and present, and consequences—while measuring behavior in an objective way. The hope was that given an adequate set of experimental results, laws and principles might be derived inductively and then tested, following the scientific trajectory already so successful in chemistry, biology and other natural sciences.

Proper controlled experiments, especially if they involve substantial rewards and punishments, are difficult, practically and ethically, with human subjects but possible with animals. Hence, the study of animal behavior has always been integral to the behavioristic approach: behaviorism was a direct outgrowth of animal-learning studies during the last decades of the 19th and the first decades of the 20th century. Two directions became highly influential: the research of Russian physiologist Ivan P. Pavlov (1849–1936) on conditioned reflexes with dogs (later called *Pavlovian* or *classical* conditioning); and American psychologist Edward L. Thorndike’s (1874–1949) studies of trial-and-error learning with cats (later called *instrumental* or *operant* conditioning). What followed Pavlov, Watson, and Thorndike was laboratory animal research that greatly expanded the range of our knowledge of learning, and pointed to novel practical and clinical applications.

History

Watson extended the work of Pavlov and Thorndike, revising some of their assumptions and theoretical inclinations. But, after a scandal involving his student-and-then-wife Rosalie Rayner, Watson left his faculty job at Johns Hopkins University in 1920 for a career in advertising. Laboratory work in the behaviorist tradition was carried on by two schools that developed during subsequent decades: the neo-behaviorist Clark Hull (1884–1952), at Yale, and cognitive behaviorist Edward Tolman (1886–1959), at Berkeley. The main experimental method involved maze learning in rats. Hull’s group tended to focus on simple habits. Tolman devised novel mazes and emphasized his idea of cognitive maps. The schools debated about the nature of the processes mediating between stimuli and responses. Should we regard behavior as a product of neurophysiology—look for *hypothetical constructs*—or just

settle for concepts that summarize empirical observations—*intervening variables*? Hull and his disciple Kenneth Spence (1907–1967) at Iowa, also sought out mathematical laws for learned behavior.

A third school, which became the most influential, developed after 1938 from the work of *radical behaviorist*, B. F. Skinner (1904–1990), at Harvard. Skinner distinguished reflexive behavior from operant behavior: A reflex is *elicited* by stimuli and is amenable to classical conditioning, as Pavlov’s studies revealed; operant behavior is *emitted* spontaneously by the organism and is amenable to operant conditioning through response-reward contiguity, as Thorndike’s law-of-effect anticipated. Animals and people are spontaneously active; their actions have consequences. With one singular exception Skinner’s empirical research involved the “power” of operant conditioning to affect the environment, to change it, and in turn to be changed by it. Skinner and others would converge on a consensus, conceiving of operant conditioning as the selection of behavior by its consequences, much as Darwin conceived of evolution by means of natural selection.

Skinner contributed immensely to psychology, with technical innovations and refinements (the cumulative record, Skinner box), empirical discoveries (especially reinforcement schedules, and *shaping* as a way to train novel behavior—discovered in a “day of great illumination” (Peterson, 2004)), theoretical interpretations of human public and private behavior, epistemological writings on method and theory, philosophical articulations and defenses of his behavioristic approach, and proposals to apply the findings of the experimental analysis of behavior to all aspects of human behavior including the treatment of mental health problems, the education of children, language and the “design of a culture.” Many of these speculations were severely criticized but Skinner rarely responded.

The study of learning in animals has also led to numerous applications. For example, after Watson and Rayner demonstrated in 1920 the acquisition of a phobia through classical conditioning in an 11-month-old boy and, four years later, Mary Cover Jones demonstrated in another infant the undoing of fear conditioning, Joseph Wolpe proposed systematic desensitization in the 1950s as a classical conditioning-based technique to eliminate a variety of phobias. For the next several decades, other psychologists started to use operant conditioning principles to help people in a variety of ways: to teach a child with autism to wear prescription glasses; to stop ruminative vomiting in a child with an intellectual disability; or to teach nurses to modify patient behavior in psychiatric wards, for example. Thus, behavior therapy and behavior modification were born, the former owing more to classical conditioning, the latter to operant conditioning. During the 1970s and 1980s, as behavior modification was re-labeled Applied Behavior Analysis, other researchers proposed to merge cognitive interventions aimed to change dysfunctional thoughts with behavior interventions aimed to change response patterns, a hybrid approach known as Cognitive-Behavior Modification or Cognitive-Behavior Therapy.

During the last three or four decades of the 20th century, as behaviorism started to lose its prominence in psychology, a third wave of behavioral researchers became influential, conducting research on a variety of topics (e.g., choice and self-control, concept learning, the interactions between learning and species-typical behavior), advancing quantitative models of behavior and learning (e.g., of classical and operant conditioning, timing); and developing research at the intersection of different disciplines (e.g., behavioral economics, psychopharmacology). In addition to the methodological, purposive, and radical behaviorisms of Watson, Tolman and Skinner, new directions for the philosophy of behaviorism were followed: Most prominently, teleological behaviorism (Howard Rachlin, 1935–2021), theoretical behaviorism (John Staddon, 1937–), biological behaviorism (William Timberlake, 1942–2019), and the partially-correct *Premack Principle* of David Premack (1925–2015), the idea that reinforcement is relative: a behavior which is more frequent under free conditions can reinforce a less frequent behavior when access is restricted.

Distinctive features

Despite their differences, the various behaviorisms share a family resemblance. By conceiving of behavior as the proper subject matter of psychology, behaviorists have always accorded fundamental importance to the environment. Behavior cannot be understood apart from the environment in which it occurs or has occurred, so much so that this idea may be the central tenet of behaviorism: Nothing in behavior makes sense except in the light of the environment—both past and present. (It is also true, but less emphasized, that nothing in behavior makes sense without some understanding of the reacting organism. Individual organisms inevitably differ in the ways they react to some environments.)

The subject matter of psychology is the environment-behavior interactions of animals and people and how these interactions affect subsequent behavior. The study of interaction yields functional relations between behavior and environment: behavioral analysis. The study of the cumulative effects of recurrent interactions is the study of the organism’s history: behavioral synthesis.

Behavioristic research began with three main learning processes. We describe those at length, and then say a little about other directions.

Habituation

A crab runs away from a growing shadow; a rat startles at a sudden noise; a 3-month-old baby turns her head to and looks in the direction of clicking keys. These reflexes have static properties—louder noises elicit stronger startle responses, for example. They also have dynamic properties, such as *habituation*: if the noise (*stimulus*) is repeated at regular intervals, the magnitude or likelihood of

the startle response will diminish, *habituate*. Habituation is perhaps the most primitive form of learning—“[habituation] occurs for virtually all behavioral responses in virtually all organisms” (Thompson, 2009, p. 128).

Habituation itself has several properties. Consider, for example, the blink response of a young baby to the sound of hands clapping every 2 s behind the child’s back (Humphrey, 1933, p. 142): “blinking occurs several times, but has generally died down by the six or seventh stimulation. Habituation has set in.”

- If the clapping stimulus is now withheld, blinking to the stimulus tends to *spontaneously recover* over time: the longer the wait before a stimulus recurs, the closer the response to its original value.
- If we then repeat the original series of habituation training, the baby habituates faster, a long-term effect of habituation.
- Weaker or more frequent clapping tends to engender faster and more pronounced habituation than stronger or less frequent clapping.
- Although a more frequent stimulus produces faster and more complete habituation, habituation persists longer (recovers more slowly) after a series of less frequent stimuli, i.e., habituation is *rate-dependent*.
- Once the baby is no longer blinking to the 2 s apart clapping hands, a strong stimulus (e.g., shaking the cradle) will reinstate blinking to the hand clapping, a property known as *dishabituation*.
- Finally, within the same stimulus modality, habituation tends to be specific to the training stimulus—just how specific can be determined by varying the stimulus during test trials and recording which of them elicit the response; the result is a stimulus *generalization gradient*.

Habituation is generally adaptive. By ignoring stimuli that are unimportant an animal can attend selectively to new or informative stimuli and respond to them exclusively. But ceasing to respond to a stimulus may incur costs—the new stimulus may sometimes be informative: the sound of rustling leaves may warn of a predator. The properties of habituation seem to be a balance between the benefits and costs of treating a repeated stimulus as “the same and harmless” vs. “possibly important.” For example, since the environment is less likely to change after a short than a long interval, one would expect faster habituation in the presence of shorter interstimulus intervals, the observed result. Conversely, it takes longer to detect that stimulation has ceased after wide-spaced than close-spaced stimuli stimulus series. Hence, habituation recovers more slowly after a slow stimulus series than a rapid one. A similar argument suggests that the effects of habituation should be reversible, and that spontaneous recovery should be more pronounced the longer the no-stimulus interval.

The next two sections discuss classical and operant conditioning. Because classical conditioning was discovered by a physiologist, Ivan P. Pavlov, and operant conditioning by behaviorists, Thorndike, Skinner, et al. they have historically been studied as separate processes. As we point out later, this separation now looks artificial.

Classical conditioning

Not all “neutral” stimuli are irrelevant. When a neutral stimulus is followed by a positively or negatively valued stimulus, such as when a ringing bell announces food or a cracking twig announces a predator, another elementary form of learning takes place: classical conditioning. The organism learns to use the neutral stimulus to anticipate the next one: whether it will be good or bad, where and when it will occur, how strong it will be. In the first systematic laboratory study of the process by Ivan Pavlov, a hungry dog heard a buzzer, the neutral stimulus, and a few seconds later the dog received a piece of meat, a biologically significant and positively valued stimulus. After a relatively long interval (say, 3 min), the buzzer-food sequence repeated. Initially, the buzzer elicited an orienting response, whereas the meat elicited the inborn reflexes of salivation, chewing and swallowing. After a few buzzer-food pairings, the orienting response to the buzzer had habituated and a new response emerged—the dog salivated upon hearing the buzzer. More generally, this new form of environment-behavior interaction occurs when an insignificant stimulus (buzzer) comes to elicit a response (salivation) because of its temporally contiguous pairing with a highly valued stimulus (meat). We abbreviate the account by saying that the buzzer became a conditional (or conditioned) stimulus (CS) by virtue of its pairing with food, the unconditional stimulus (US). The salivation (and much else, as we will see) is the conditioned response (CR).

Classical conditioning is involved in the acquisition of emotional responses in humans. A child bitten by a dog or simply exposed to a barking dog may fear the animal, or dogs in general, subsequently. The event constitutes a conditioning trial: The dog is the CS; the biting or barking is the US; the fear elicited by the US is the unconditional response (UR) and the fear acquired to the CS is the CR. Fear may also be acquired simply by observing another person showing intense fear in the presence of, say, a snake, an ancient enemy.

Behavioral psychologists have studied classical conditioning extensively. Using a variety of laboratory preparations, they have examined the factors that determine whether, how well and how fast a CS-US association is learned or unlearned; the kinds of associations (e.g., excitatory, inhibitory) that can be learned (easily, with some difficulty, or hardly if at all); the form and strength of the CR; or the effects of learning on other stimuli. Psychologists have also developed theories and models to explain what is learned in classical conditioning, and to predict the effect of multiple stimulus and other more complex stimulus arrangements. These evolving theories have also inspired application of classical conditioning to socially relevant problems.

Acquisition

Whether an organism will learn a CS-US association depends on multiple factors including properties of the individual stimuli and their combination (type and salience of CS and type and strength of the US), the temporal and probabilistic relations between the stimuli, and the organism's history with those and similar stimuli. Classical conditioning is anything but simple!

To illustrate, humans and rats readily associate a new taste with a subsequent gastrointestinal illness, even if the illness, the US, is delayed by an hour or more from the taste CS. But rats have difficulty associating visual stimuli even with immediate illness. In contrast, crows readily learn to associate the visual cues of a poisonous monarch butterfly with the illness it causes. Taste-aversion learning (crows included) has two distinctive features: Only one CS-US pairing is required to learn the association, and the CS-US delay may be several hours. Other forms of classical conditioning require more pairings and shorter CS-US delays.

Within a preparation, the timing of the CS and US stimuli may have major effects on the strength of the CR, on the moment this response occurs, or on whether the CS will predict the presence or absence of the US. All else equal, it is easier to associate buzzer and food when a short interval separates them. When that interval is long, the subject may be unable to learn the association. However, if the delayed pairing occurs very intermittently, so that the US is indeed more likely after the CS than in its absence, some conditioning will occur. This is called a predictive *contingency*. Moreover, if we start with a short interval and increase it as the subject learns the association, by the end of training the dog may be salivating to the buzzer despite the long interval separating it from food. This is a critical but poorly understood learning principle (Pear, 2016).

With long CS-US delays, such as when a buzzer announces food 3 min later, the subject also learns to time its response to the buzzer: The dog will salivate during the last 20 or 30 s preceding the arrival of food. But if the buzzer-food order reverses (the food precedes the buzzer), the dog is likely to learn an inhibitory association, as the buzzer now announces the absence of food.

Similar studies with humans have examined how probabilistic relations between stimuli affect our judgments of their association. In a contingency judgment task, a participant reads scenarios in which events of type A and type B (akin to CS and US) may or may not co-occur. In the food allergy paradigm, for example, A may be the ingestion of a particular food and B an allergy. Afterward, the participant judges the strength of the relation between A and B. The goal is to understand how we form contingency judgments, how we set their positive or negative direction and their strength as a function of, among other factors, the stimulus occurrences and our prior experiences with them.

The learning of a particular CS-US association may depend on the learning taking place with other stimuli. For example, if food is already anticipated by a buzzer due to previous training, adding a light to the buzzer just before each new episode of food will not change the dog's behavior toward the light. This is called *blocking*. (There is a related effect called *overshadowing*: when two stimuli one highly salient, the other not, have the same predictive relation to the US, conditioning may occur only to the more salient stimulus, even though conditioning would have occurred to the less salient, had it been presented alone.)

Going one step further, a stimulus may become a CS (and elicit a new response) even without being paired with a US (e.g., food): pairing it with another CS may suffice. In the prototypical setting, a dog may learn to salivate to the sound of a metronome if the metronome is paired systematically with a previously conditioned, food-associated buzzer. In this case, the buzzer is a first-order conditional stimulus (CS1) because it is paired with food (US), and the metronome is a second-order conditional stimulus (CS2) because it is paired with a first-order CS. Although the CS2 is never paired with food, it nevertheless elicits salivation (*second-order conditioning*).

Second- and higher-order conditioning explain partly how we learn to like or dislike objects. Pairing an abstract, geometric drawing with an attractive picture (e.g., a pretty face) or a nice word (e.g., "honest"), for example, tends to change the drawing's valence from neutral to positive; pairing it with a threatening or disgusting picture, or with an unpleasant word such as "arrogant", tends to change its valence from neutral to negative. These examples of evaluative conditioning, used abundantly in advertising, seem to involve the transfer of value from first-order CSs (the positive or negative pictures or words) to second-order CS (the abstract drawing). Our impressions of a person may also depend on classical conditioning (e.g., when, on first meeting John, we hear a mutual friend describe him as "friendly"). First associations may even be more resistant to change than subsequently learned ones.

Extinction

Once an association is learned, how can it be unlearned? Let us return to the prototypical example. If the buzzer is presented without the food, the dog will salivate less and less to the buzzer and eventually will stop salivating to it. Presenting a CS without the US attenuates the CR and may even eliminate it, a procedure known as extinction. The procedure immediately suggests a way to treat nonadaptive emotional responses elicited by specific stimuli. Expose the subject to the phobic stimulus and ensure that no aversive event occurs during the exposure. In one variation of the procedure, *flooding*, the subject faces a strongly feared stimulus or a series of increasingly more fearful stimuli. In another, in-vivo systematic desensitization, the gradual exposure to more fearful stimuli occurs while the subject is in a relaxed state. Extinction-based exposure techniques are key ingredients of the most effective psychotherapies for anxiety.

But extinction of the CS-US association does not seem to be the simple undoing or reversing of the acquisition of the CS-US association. Part of the evidence is that the effects of extinction are often restricted to the extinction context—the buzzer that no longer elicits salivation in the extinction context may readily elicit salivation in a new context. Similarly, reencountering the US in the absence of the CS—the dog receives food in the absence of the buzzer—may suffice to reinstate salivation to the buzzer. Even the mere passage of time without further occurrences of buzzer or food may recover the response to the buzzer. These renewal,

reinstatement, and spontaneous recovery effects suggest (but the issue is far from settled) that extinction may involve the learning of inhibitory and context-dependent CS-US associations. Be that as it may, the study of extinction is helping applied psychologists understand the relapse of emotional reactions after their successful treatment and how to prevent them. As Vervliet et al. (2013) put it, learning theory “provides a continuous source of inspiration for new developments in the field of fear extinction and return” (p. 219).

Emitted behavior and the form of the conditioned response

Because classical conditioning was first studied in a physiology lab, the focus was on the autonomic response of salivation. But the procedure itself actually leads to much broader effects. In fact classical and operant conditioning are inseparable: classical conditioning, which has effects on both autonomic and somatic behaviors, provides the repertoire from which contingent *reinforcement* (i.e., reward produced by, and usually immediately following a response) can select.

Operant behavior is *emitted* according to processes never well defined, but presumably including the motivational state of the organism, its past history and current environment. Contingent reinforcement then selects from this emitted repertoire. Respondent behavior, on the other hand, is often spoken of as *elicited* by a neutral stimulus (the CS) that predicts an unconditioned stimulus (US) such as food (which can act as a reinforcer in an operant situation).

The distinction between “emitted” and “elicited” corresponds to no observable property: a rapid learned response may be as swift as an eyeblink conditioned reflex. But the prototypical reflex response was Pavlovian salivation, run by the autonomic nervous system, as opposed to operantly conditioned pecking, run by the somatic system. These differences are presumably what led Skinner to characterize behavior conditioned in the Pavlovian way (classical conditioning) as *respondent* and behavior conditioned by contingent consequences as *operant*—to treat them as two quite separate classes. In the same way, the field of animal learning as a whole was pretty clearly divided into operant vs. classical conditioners.

The distinction was challenged in 1968 when Brown and Jenkins published a paper on what they called *autoshaping*, although this was not clear at the time. Even though the procedure was purely Pavlovian, a 7 s light followed by food reward presented every minute or so, naïve pigeons swiftly learned to peck the light. Yet these anomalous results were at first seen in terms of the old paradigm, as the outcome of familiar operant processes: “[O]ur account essentially parallels the accounts offered by Skinner (1948) and by Morse and Skinner (1957) for the first and second types of superstitious behavior.”

The result was indeed Pavlovian conditioning, but not of salivation but *pecking* of the lighted key. These findings were soon corroborated by others, but none emphasized the obvious contradiction between the autoshaping result and the operant-respondent distinction. Here was pecking, the favored Skinnerian operant, behaving just like a respondent.

There had been earlier hints that a Pavlovian procedure can induce operant behavior. For example, a visitor to Pavlov’s lab noticed that if a trained dog is out of its usual harness, his first response to the conditioned stimulus was “the whole system of behavior patterns serving, in a number of *Canidae*, to beg food from a conspecific. It is, in fact, this whole system that is being conditioned in the classical experiment” i.e., operant not respondent behavior. The dog had developed an *expectation*, which implies a repertoire of food-related activities including, but not limited to, salivation.

The essential identity of the processes underlying operant and Pavlovian conditioning got additional support from a replication (Staddon and Simmelhag, 1971) of Skinner’s famous Pavlovian “superstition” experiment, which simply involved giving a hungry pigeon a bit of food every 15 s (*temporal conditioning*). Skinner reported the development of vigorous stereotyped behavior that Skinner interpreted as the result of *adventitious* (accidental) *reinforcement* of random behavior by the pigeon. When the experiment was repeated, but with more detailed temporal recording of the resulting behavior, the authors found at least two kinds of induced behavior: the *terminal* response, toward the end of the interfood interval, which in this case was just pecking, usually at the chamber wall above the feeder aperture, since there was no stimulus key—and what was called *interim* behavior, other activities that occurred earlier in the 12 s interfood interval. The interim behaviors were rarely contiguous with food, hence not operant in the conventional sense. And the terminal response was clearly operant.

A still-developing resolution of the problem is abandonment of both the operant-respondent dichotomy and the stimulus-response framework. For stimulus substitute *situation*, and for response substitute the *state* of the organism, where the state defines not a single response but a *repertoire* of potential actions. The range of behavioral variation depends on how “hot” (predictive of reinforcement) the situation is, and how the organism is constrained. At the high end, the repertoire is limited, and the organism displays rigid behavior typically associated with classical conditioning. In the middle we see a wide range of “emitted” behavior, available for selection by contiguous reinforcement. At the low end, the repertoire is again limited until the situation looks more promising. The shift from rigid stimulus-response links to the more Darwinian selection of a response from a repertoire associated with the state of the organism, controlled by its history and present situation, seems to represent a more realistic view of how learning works—in animals and perhaps in humans as well. The distinction between classical and operant conditioning remains, not as two separate processes but simply as labels for two different procedures.

Classical conditioning seems to be involved in problems of drug addiction. The direct drug effects (e.g., analgesia, hypothermia) constitute the US. The responses that the body produces to compensate for these effects constitute the URs. They have a regulatory or homeostatic function, to preserve the “internal milieu” in the presence of the severe disruption caused by the US. The cues accompanying the primary drug effects (e.g., the injection, the location) are the CSs; after a few pairings with the US, these CSs elicit the compensatory CRs (e.g., hyperalgesia, hyperthermia). These CRs contribute to chronic drug tolerance, the fact that a specific drug dose becomes less effective with repeated administrations of the drug, a kind of habituation. To experience the original drug effect,

the user increases the dose, but a higher dose also conditions stronger compensatory responses, which again reduce the drug effects. The process may spiral up and the user may reach a high dose that would have been fatal if consumed on the first day, without the benefit of the compensatory responses. In fact, at this moment the user may be at a higher risk of death if he consumes the drug in a new environment, one with few or no cues associated with the drug administration and therefore without the protective effect of the conditioned compensatory responses (a kind of dishabituation). Moreover, if drug-associated cues are present but the drug is not consumed, the compensatory responses themselves will not be attenuated by the drug effects. The full expression of the compensatory CRs contributes to the withdrawal symptoms (Siegel, 2008, 2016). Research on classical conditioning has direct implications for the treatment of addictions—finding ways to minimize conditioned reactions to a variety of cues, for example.

Operant conditioning

Operant conditioning is the way that most “higher” animals learn. The prototypical operant conditioning experiment is a hungry rat that is rewarded (reinforced) with food for pressing a lever. It may have learned by just emitting behavior at random, until it presses the lever and gets fed. Or it may have been *shaped* by being rewarded when it gets close to the lever. Or, like the autoshaped pigeon, the desired behavior may have been produced by classical conditioning, all in the service of facilitating a repertoire of behavior, a state, of which the target behavior is a member.

Extinction and reinforcement schedules

If a learned operant response is no longer reinforced—lever pressing no longer yields food—response rate decreases. This extinction process is often accompanied by emotional responses (e.g., biting the lever, pressing it harder). Between the extremes of continuous reinforcement, with each response reinforced, and extinction, with no response reinforced, lies partial or intermittent reinforcement, with only some responses reinforced. The rule specifying which responses will be reinforced defines a *reinforcement schedule*. Two examples are *variable ratio* schedules in which each response has a fixed probability of payoff, and *fixed interval* schedules, in which a response is reinforced provided a fixed interval of time has elapsed since the previous reinforcer.

Much operant conditioning research is devoted to the effects of reinforcement schedules on the rates and probabilities of responding, on the distribution of responses across time, and on the resistance of responses to extinction. For example, moderate-size variable ratio schedules (analogous to the gambler’s one-armed bandit device) generate vigorous, sustained rates of responding and great resistance to extinction.

Shaping

A “free” reinforcer may tell the organism it is in a food situation so it may emit food-related behaviors. But if one of those is reinforced, the animal’s repertoire is unlikely to increase further. How then do animals and people learn novel and sometimes complex behaviors (e.g., the choreographies performed by dogs with their trainers; the acrobatic moves of dolphins at water parks)? The usual method is *shaping*, the differential reinforcement of successive approximations to a target behavior. In each stage, a behavior closer to the target response than in the previous stage is reinforced while other behaviors are not.

Shaping may sometimes occur naturally. Field observations have shown that some rats living along the banks of the Po River in Italy dive for and feed on mollusks inhabiting the river bottom. This unusual behavior may have developed because wide, natural fluctuations in the water level first expose the mollusks and then gradually resubmerge them, creating the conditions for the rats to learn to dive for food by natural shaping (Galef, 1980). Another case of natural shaping may involve the female cowbird’s reaction (the reinforcer) to young male cowbirds singing. Wing stroking by females correlated with faster rate of song development in males; it was also related to differences in song potency. This non-vocal shaping process may be like the processes that influence phonological development in human infants (King et al., 2005; Goldstein et al., 2003).

Shaping is common in everyday human life, as children learn to dress, swim, write the alphabet, or read, for example. It has been used extensively in applied settings to teach rudimentary language skills to autistic children, appropriate behavior to severely psychotic patients, and complex performances to professional athletes. Shaping is also used to train cooperative behaviors in zoo animals.

Aversive control: reinforcement and punishment

Operant behavior increases following a reinforcement and decreases in probability after an *aversive stimulus: punishment*. There are two types of punishment: either an aversive stimulus is presented to the subject (e.g., a reprimand given to a child), or a reinforcer is taken away (e.g., the cell phone is taken away from a teenager). In the laboratory, by adjusting the parameters of the punisher (e.g., its intensity, delay, schedule), behavioral psychologists have identified several regularities (e.g., immediate is more effective than delayed; after every unwanted response is more effective than occasionally, etc.). B. F. Skinner often declared that punishment is an ineffective way to control human behavior. But the available animal research does not support this conclusion. More needs to be known, but unfortunately the laboratory study of punishment has almost ceased, for a combination of ethical and regulatory reasons.

Stimulus control: discrimination and generalization

Operant conditioning stresses behavior-outcome relations, but these relations typically hold only under specific conditions. Pecking a colored key produces food only if the key is this color in this Skinner box. A stimulus in the presence of which a response is likely to be reinforced is termed a *discriminative stimulus* (S^D). The fox is likely to obtain a meal by chasing the rabbit (the S^D) but not by chasing the hound; the child is likely to receive a smile by saying “daddy” in front of her father (the S^D) but not to a stranger. The fox and the child have learned a stimulus discrimination, to respond differently in the presence of different stimuli. Of course, the fox chases not just a single rabbit but a class of rabbits (e.g., white, gray, or black); chasing shows stimulus generalization. In fact, a finer analysis would certainly reveal that the likelihood of chasing the rabbit, or the vigor of the chase, vary with other stimulus attributes (e.g., color, size, and distance of the rabbit).

To study how a neutral stimulus may come to control a given response, that is, how an S becomes an S^D , researchers in the laboratory alternate the reinforcement of that response in the presence of S with the extinction of the response in the absence of S . In a Skinner box, a rat receives food pellets for pressing a lever when a light is on but not when the light is off, with each stimulus condition alternating every 3 min. If we peek into the Skinner box after a few days, we will see that when the light is turned off the rat engages in behaviors other than pressing the lever; when the light is turned on, the rat mainly presses the lever and eats the food.

By varying the stimulus, the response, the reinforcement schedules, and a host of other variables, behavioral psychologists have found many regularities concerning the acquisition and maintenance of stimulus control, how organisms attend and respond to selective features of their environment, how they generalize, and how they learn complex discriminations and discriminative repertoires. Their techniques and findings have been used to investigate a broad range of issues, ranging from animal psychophysics (e.g., do animals also have visual illusions?) and behavioral neuroscience (e.g., what is the role of neurotransmitter dopamine in temporal discriminations?) to problems of applied educational, organizational, and clinical psychology (e.g., how to decrease off-task behaviors in the classroom, train complex skills in a factory, or treat self-injurious behaviors).

Conditioned reinforcement, chains, and delay-of-reinforcement gradient

A reinforced response is always learned in a particular stimulus situation (the *discriminative stimulus*, S^D); this is Skinner’s *three-term contingency*. If the situation is changed, the response will not occur, or will be weaker. Not surprisingly, the S^D often becomes a conditioned or secondary reinforcer, a stimulus that can be used to strengthen behavior.

Chains of responses may thus be learned, with one and the same stimulus serving as the reinforcer of the response that precedes it and as the discriminative stimulus for the response that follows it. The actual causation is more complex, though: the reinforcing property of a stimulus weakens the farther back, in time or in the chain it is from the primary reinforcer. Chaining has been used in many applied settings. Recently, with a clicker in the role of conditioned stimulus, chaining was used successfully to teach complex procedural surgical skills (e.g., tying knots, making low angle drilling holes) to medical students (Levy et al., 2016).

The initial link of the chain announces a delayed reinforcer at the end of the chain. The teacher instructs the student to solve the first five homework problems before going to recess. Whether the child attends to the initial-link stimulus, the instruction, and whether she continues to respond throughout the delay as other stimuli occur, may depend on the child’s delay-of-reinforcement gradient, that is, on how rapidly reinforcement value, V , decreases with delay, D . Many studies have yielded results consistent with the function

$$V(D) = \frac{V_0}{1 + kD}, \quad k > 0$$

where V_0 is the value of the reinforcer without delay and k is a delay discounting parameter. A steep gradient (large k) may mean that the stimuli at the beginning of the chain may not reinforce adequately the behavior of attending to them, and the child’s attention will wander off task. Moreover, steep gradients may also select rapid responding over slower responding because only when behavior occurs rapidly will the final reinforcer affect the beginning of the action. In addition to attention problems, steep gradients may engender hyperactive behavior, as in children with attention-deficit hyperactivity disorder (Sagvolden et al., 2005).

Choice, matching and self-control

Reinforcers vary along multiple dimensions. A primary reinforcer such as food, for example, varies along quality, amount, probability, delay, and other dimensions. Discovering how each dimension affects behavior, separately and in combination, is a difficult but critical task if we are to understand naturally occurring behavior. Suppose we have a choice between two behaviors, B_1 and B_2 (e.g., dining at Chinese or Italian restaurants; in a classroom, engaging in on-task or off-task behaviors; calling John or Mary on the phone for a chat). Behaviors B_1 and B_2 produce reinforcers at rates R_1 and R_2 , respectively (how often we experience excellent meals at each restaurant, receive attention from classmates from each behavior, or have comforting conversations with each friend). What determines how we choose or, more specifically, how often we engage in one or the other behavior? Depends on the schedule. A simple choice amounts to a fixed-ratio schedule and most organisms respond optimally: they pick the best option exclusively. On the other hand, as economists and biologists well know, most reinforcers *satiates*: the more you get the less attractive each increment becomes. So, even when the schedule is FR1, subjects will often switch from the option initially favored after a while.

The same result can be obtained as a steady state if the two choices are available on variable-interval schedules (*concurrent VI VI*), since the probability of payoff for the disfavored choice, hence its attractiveness relative to the favored choice, increases with time away. Much research has been done with this rather complex procedure because the functional relations obtained by varying the values of the VIs associated with each choice are both simple and readily reproducible.

Given two choices, $B1$ and $B2$, the usual steady-state result is the so-called generalized matching law: The ratio of responses in a typical experimental session of an hour or two, $B1/B2$, is a power function of the ratio of obtained reinforcers, $R1/R2$:

$$\frac{B1}{B2} = b \left(\frac{R1}{R2} \right)^s, \quad 0 < s < 1$$

where s is a sensitivity parameter and b is a bias parameter. Given another procedural feature called a change-over delay, which prevents switches from being immediately reinforced, s and b tend to approach 1, which is Richard Herrnstein's initial formulation of his *matching law*.

But suppose the reinforcers for behaviors $B1$ and $B2$ vary along the dimensions of amount and delay, in fact, that they trade amount for delay: $B1$ yields more reinforcers than $B2$, but those reinforcers are also more delayed. All else equal, we know that more is better than less and immediate is better than delayed, but which is better, more/delayed or less/immediate? And how does value—and hence choice—change as the delays elapse? These questions are at the heart of research on self-control and impulsivity. In a typical laboratory situation, a pigeon may choose between 6 s of access to food (large reward) but delayed for 10 s, and 2 s access to food (small reward) delivered after 2 s. Similarly, a child may choose between two marshmallows after a 5 min waiting period, or one marshmallow immediately. Self-control is equated with the choice of the large-later reward, impulsivity with that of the small-sooner reward. Psychologists have studied empirically how choice depends on the magnitudes of the options, the choice context, prior learning experiences (e.g., learning what to do during the waiting period), and the species and developmental stage of the organism. They have also developed theories and models to predict preference for the self-control or the impulsive options, the reversal of preference from the former to the latter, and how to prevent such reversals in applied settings. The conc VI VI procedure is undoubtedly a useful tool for measuring the behavioral effects of these parameters. But because of the negative feedbacks built in to the concurrent VI VI procedure, the extent to which the beautiful regularities it yields are due to the organism and how much to the procedure, are still unclear.

Behavioral psychology and education

One of the distinctive features of behavioral psychology is its historical approach to the explanation of behavioral patterns. Instead of moving in space, from without to within the organism in search of inner cognitive or neurophysiological processes that generate behavior, the behavioral approach moves in time, from the present to past behavior-environment interactions in search of ways to understand how current behavior resulted from the integration of the effects of recurrent causes, each perhaps with a small effect, operating over long periods of time. The behavioral explanation is not unlike the historical explanation of an adaptive biological structure (e.g., the vertebrate eye) in terms of the cumulative effects of natural selection acting consistently over long stretches of time.

A correct behavioral account brings with it the immediate benefit of identifying how to implement specific kinds of behavior-environment interactions to promote desirable behaviors and reduce or prevent undesirable behaviors. A case in point is the Good Behavioral Game (GBG), a remarkably simple behavioral strategy that implements group-based contingencies to reduce disruptive classroom behaviors and promote academic engagement and prosocial behaviors. In its simplest version, teacher and students identify the rules that would make the setting a good place to learn, more enjoyable and pleasant, as well as the rules or "fouls" that would interfere with the desirable outcomes. The game is played at specified intervals (e.g., math class, reading class). The group is divided into two or more teams, and the team with the least number of fouls wins the game; alternatively, any team with the number of fouls below a criterion wins the game (this reinforcement rule is a group variant of a schedule known as differential reinforcement of low rates of behavior). A highly visible scorecard shows daily the fouls and wins of each team. Additional features of the game apply to different contexts and populations (e.g., students with emotional disorders, undergraduate students, preschool children).

Developed in 1969 by Barrish, Saunders, and Wolf, the GBG has been studied extensively since then. Its positive effects on student behavior were immediate. Other positive effects, however, were revealed only in long-term follow-up studies. In 2002, Embry remarked: "[The Game] worked pretty well," and became a behavior-modification "trick" most graduate students in behavior analysis or special education learned during the heyday of behavioral psychology. Neither Barrish, Saunders, or Wolf, nor the graduate students who learned to use the Game as a classroom strategy, had the slightest idea then how powerful the strategy might be for changing the future of children destined for multiple lifetime problems of substance abuse, violence, and school failure. In 2011, Kellam et al. summarized the results of a large-scale randomized control trial study that tested the game with first- and second-grade children with a follow-up at ages 19 to 21: "significantly lower rates of drug and alcohol use disorders, regular smoking, antisocial personality disorder, delinquency and incarceration for violent crimes, suicide ideation, and use of school-based services among students who had played the GBG. Several replications with shorter follow up periods have provided similar early results" (p. 73).

The legacy of the behavioristic approach

Behaviorism was the dominant school of psychology until about the last quarter of the 20th century. Its demise has been reported multiple times. On the other hand, no field that is still divided into “schools” can claim to be a mature science: there are no schools of physics or chemistry, or even biology. In fact all scientific psychologists are behaviorists of a sort, for they all share a commitment to objective methods and measurements—to draw inferences about learning and memory, for example. The difference is cumulativeness and the reality of theoretical entities. As we have described, behaviorism has progressed. We know more now about reinforcers and punishers and how they work, the complementary relation between classical and operant conditioning, why reinforcement schedules have the effects they do. Much more research is always needed, but the direction of advance is clear. Unfortunately the variants of cognitive psychology have not progressed in this way. Instead they have adopted questionable experimental methods (the replication crisis is an almost inevitable product of the almost-universal Null Hypothesis Significance Testing group-experimental method) and settled prematurely on the digital computer as a model for the mind. With a few exceptions, such as the early work of Jean Piaget, the nominal fallacy is rampant: experimental results in very restricted situations are said to measure things like self-efficacy, craving, self-enhancement, confirmation bias, etc., whereas real scientific concepts cannot just be labeled into existence but must be derivable from a theory with many testable predictions.

There is a deep irony here. On the one hand, psychology remains a fragmented science, more so with each passing decade. Currently, the American Psychological Association lists 54 divisions, a name befitting their effect. Anthropologist Geertz (1997) described the view from the outside: “[Psychology] looks like an assortment of disparate and disconnected inquiries classed together because they all make reference in some way or other to something or other called ‘mental functioning.’ Dozens of characters in search of a play” (p. 22).

On the other hand, the applications of behavioristic psychology remain unrivaled, even after four or five decades of cognitive psychology. De Houwer and Hughes (2020) summarize, after covering the main concepts of classical and operant conditioning:

[These concepts] (...) form the core of treatment programs that are dramatically improving the lives of millions of children and adults living with developmental and intellectual disabilities (...). They are shaping people into better parents, teachers, colleagues, and friends (...). They are being used to radically cut drug and alcohol use in people struggling with addictions (...). Concepts and procedures derived from the psychology of learning are the beating heart of many clinical therapies used to treat phobias, panic and anxiety disorders, and chronic pain—related issues, as well as psychosis, depression, and substance abuse (...). Those same ideas are deployed to train disobedient pets and improve the welfare of zoo animals and livestock (...), address health behaviors (...), help athletes improve their performances and pathological gamblers beat their addictions (...), promote recycling and reduce pollution (...), and much, much more (...). The takeaway message is that the procedures, effects, and principles [of classical and operant conditioning] ... drive human behavior and can help us save lives and improve well-being (p. 201).

If psychology is ever to be a science, if it is to be of practical use, it will be behavioristic.

Contemporary theories of learning predict that learners are active seekers and processors of information (Mayer, 2012). They do not passively absorb information from the environment but rather proactively develop new knowledge by influencing what, where, why, when, and how they learn.

Social cognitive theory reflects this proactive self-regulatory emphasis. Social cognitive theory predicts that much human learning occurs in social environments. By interacting with others live or virtually, people learn knowledge, skills, strategies, beliefs, rules, and attitudes. They also learn about the appropriateness, usefulness, and consequences of behaviors. People act in accordance with their beliefs about their capabilities and the expected outcomes of actions.

Although there are different social cognitive perspectives, this chapter focuses on the theoretical perspective formulated and developed by Bandura (1977b, 1986, 1997, 2001). This theory highlights the key roles played by vicarious, symbolic, and self-regulatory processes, in the learning and performance of actions.

The next section describes historical influences on social cognitive theory and Bandura's early studies investigating social modeling. Then the conceptual framework of Bandura's theory is discussed. Subsequent sections describe the key roles played

by vicarious, symbolic, and self-regulatory processes. Some educational implications of the theory and research are given, and suggestions for future research are provided. It is hoped that this chapter will promote research on and development of social cognitive theory as a perspective on learning.

Background

Historical influences

There are several historical influences on Bandura's social cognitive theory. Three noteworthy ones are imitation, latent learning, and social learning.

Imitation

Historical perspectives on imitation postulated that people were naturally inclined to imitate the actions of others (James, 1890). McDougall (1926) believed that observing actions of others elicited an instinct in observers to copy those actions. Early behaviorists (e.g., Watson, 1924) dismissed this instinct notion because it assumed the existence of an inner drive that intervened between a stimulus (observed action) and response (copying that action).

Behaviorists initially postulated that imitation was conditioned. Skinner (1953) predicted that imitation represented a generalized response class that could be explained using a three-term contingency: discriminative stimulus → response → reinforcing stimulus. An observed action was the discriminative stimulus. Imitation occurred when an individual performed that action (response). If the response was reinforced (reinforcing stimulus), this reinforcement increased the future likelihood of imitating the actions of others. Because imitation was reinforced by different people under various conditions, the act of imitating became a generalized response class.

This view assumes that individuals can perform the imitated response. Yet much research shows that various types of behaviors can be learned by observing models (Rosenthal and Zimmerman, 1978). Another issue is that for imitation to occur it must be reinforced. Researchers have shown that modeling can occur without any external reinforcement (Bandura and Walters, 1963).

Latent learning

Latent learning is learning that occurs without reinforcement. In a seminal study, Tolman and Honzik (1930) let rats wander through a maze. Some rats always were fed in the maze and others were never fed. Rats fed in the maze quickly reduced their time and errors in running the maze, whereas time and errors for the other group did not diminish. Later, some rats from the nonreinforced group were given food for running the maze. Their time and number of errors quickly decreased to the levels of those who always had been fed, whereas the time and errors for rats who continued not to be reinforced did not change. Thus, rats in the nonreinforced group learned features of the maze by running through it without being reinforced. When food was given, latent learning was displayed.

Latent learning research showed that learning can occur when not displayed at the time of learning and that reinforcement affected performance of behaviors rather than learning. This distinction between learning and performance is central to Bandura's social cognitive theory. Because latent learning research involved animals, it could not explore such cognitive processes as goals and expectations, and not fully establish the potential of latent learning.

Social learning

Rotter (1954) developed a social learning theory of personality that was applied to learning. The theory included four primary variables: behavior potential, expectancy, reinforcement value, and the psychological situation. Behavior potential referred to the probability that an individual would act in a given way relative to alternative behaviors. This potential depended on the individual's expectancy (belief about the likelihood of reinforcement occurring as a consequence of behavior), and on reinforcement value (how much the individual valued a particular outcome relative to other potential outcomes). The psychological situation referred to the context of behavior. Through social interactions with others, people formed expectancies about the likely outcomes of actions, and they acted in accordance with their expectancies and the value they placed on the potential outcomes.

Rotter's theory represented an important advance over behavior theories because it showed that people act based on what they believe rather than in accordance with prior reinforcement. When beliefs contradict prior experience (e.g., a behavior has been reinforced but now people believe it will not be), people follow their beliefs.

Rotter's theory, however, only considered beliefs about potential outcomes of actions. Bandura's social cognitive theory includes these outcome expectations but also postulates influential roles for other cognitive beliefs including goals, self-efficacy, and self-evaluations of learning and goal progress (discussed later in this chapter).

Early modeling studies

Early studies by Bandura and his colleagues contributed to the development of contemporary social cognitive theory (Bandura, 1977b). In a classic demonstration of observational learning, Bandura et al. (1963) exposed children to live aggressive models, filmed aggressive models, aggression by cartoon characters, or no models. The models pummeled a Bobo doll by hitting, throwing, kicking, and sitting on it. Models were not rewarded or punished for their actions. Children subsequently played with a Bobo doll. Compared with no-model control children, children exposed to aggressive models displayed significantly higher levels of

aggression. Type of aggressive model (i.e., live, filmed, cartoon) made no difference in children's levels of aggression. The results suggested that children learned from observing models and that the consequences of modeled actions did not affect learning.

In addition to overt behaviors, researchers also demonstrated that people can learn cognitive rules from observing models. Bandura and Harris (1966) had models show children common nouns and sentences with each noun. Some children viewed models who demonstrated the desired construction (e.g., passive verbs) and who then took turns with them in constructing sentences. Reinforcement was given to some children for constructing passive voice sentences. Problem-solving set children were told to determine what type of construction earned them reinforcement.

Although the use of passive constructions by children was low following the experimental treatments, modeling combined with reinforcement and problem-solving set led to the highest number. Children did not imitate the models but rather acquired the grammatical rule and constructed their own sentences. Further evidence of rule learning was obtained in an early study by Rosenthal et al. (1971). Collectively, these studies showed that people learn from observing models and that reinforcement was not needed for learning.

Conceptual framework

The conceptual framework of Bandura's social cognitive theory is based on reciprocal interactions among personal, behavioral, and social/environmental factors. This section also discusses enactive and vicarious learning, as well as vicarious, symbolic, and self-regulatory processes.

Reciprocal interactions

A central tenet of Bandura's (1977b, 1986, 1997, 2001) social cognitive theory is that human psychological activity depends on *triadic reciprocity* involving reciprocal interactions among three sets of influences: personal (e.g., cognitions, beliefs, skills, affects); behavioral; and social/environmental factors. Individuals' cognitions and environments can affect their behaviors, which in turn can alter their environments and subsequent personal influences (Fig. 1).

These interacting influences can be exemplified using *self-efficacy*, which is a personal factor defined as one's perceived capabilities for learning or performing actions at designated levels (Bandura, 1977a, 1997). With respect to the interaction of self-efficacy and behavior, researchers have shown that self-efficacy influences achievement behaviors such as task choice, effort, persistence, and use of effective learning strategies (Schunk and DiBenedetto, 2016). These behaviors also affect self-efficacy. As students work on tasks and observe their learning progress, their self-efficacy for continued learning is enhanced.

The influence between personal and social/environmental factors can be illustrated with students with learning disabilities, many of whom hold low self-efficacy (Licht and Kistner, 1986). Individuals in their environments may react to them based on common attributes (e.g., low skills) rather than on actual capabilities. In turn, social/environmental feedback can affect students' self-efficacy, such as when a teacher tells a student "I know you can do this."

The link between behaviors and social/environmental factors is seen in many instructional sequences. Social/environmental factors direct behaviors when a teacher points to a display and says, "Look here," which students do without much conscious effort. Students' behaviors can alter their instructional environments. When teachers ask questions and students give incorrect answers, teachers re-teach the material rather than continuing the lesson.

Bandura's social cognitive theory reflects a view of human *agency* in which individuals proactively influence their lives (Schunk and Pajares, 2005). They hold beliefs that allow them to exert a large degree of control over important events in their lives. People who want to become musicians take music lessons and get mentoring from experienced musicians. In reciprocal fashion, people influence and are influenced by their actions and environments. Music students change their behaviors and environments in response to feedback from their mentors.

Fig. 1 Triadic reciprocity in social cognitive theory.

The scope of this reciprocal influence is broad because individuals live in social environments. *Collective agency* refers to people's shared beliefs about what they are capable of accomplishing as a group. Like individuals, groups also affect and are influenced by their actions and environments. A group of science teachers may collectively decide to use more project-based learning to deepen students' understanding of scientific concepts. They develop and implement activities and continue to refine them based on students' learning.

Enactive and vicarious learning

Social cognitive theory distinguishes *enactive learning* (doing) from *vicarious learning* (observing modeled performances—live, filmed, symbolic; Bandura, 1977b). Behaviors that result in success are retained, whereas those that are unsuccessful are discarded or modified. Social cognitive theory contends that behavioral consequences inform and motivate. They inform people of the accuracy or appropriateness of behaviors. People who are rewarded for their actions understand that they are performing well, whereas punishments convey inappropriateness of behaviors. Further, people are motivated to learn and perform behaviors that they believe will have desirable consequences and do not try to learn behaviors that they believe will be punished.

Much human learning occurs *vicariously*, or without learners performing at the time of learning. Vicarious learning accelerates learning over what would be possible if people had to perform every action, and it saves people from undesirable consequences. Observing or reading about safety techniques saves individuals from acting in potentially dangerous ways. As with enactive learning, observers are more motivated to learn actions leading to successes than those that are unsuccessful. People attend to successful models who demonstrate actions that they believe will benefit them (Bandura, 1969; Schunk, 1987).

Much human learning occurs through a blend of enactive and vicarious learning. Learners observe teachers explain and demonstrate skills and strategies. By observing teacher models, students may learn some aspects of skills. As students practice the skills, teachers provide feedback and corrective instruction as needed.

Vicarious, symbolic, and self-regulatory processes

Bandura's (1986) social cognitive theory postulates that human capabilities facilitate individuals attaining a sense of agency. Vicarious, symbolic, and self-regulatory processes are prominent capabilities.

The capability for learning vicariously allows individuals to acquire knowledge, beliefs, affects, and behaviors, by observing others. This capability also allows people to develop their lives because they proactively select environmental features (e.g., individuals, materials) to which they want to attend. People who want to learn about Mars seek out situations where they can learn vicariously, such as by reading books, watching televised shows, attending lectures, and so forth.

Symbolic capabilities involving language and mathematical and scientific notation allow people to adapt to and alter their environments (Bandura, 1986). They use symbolic processes to interpret actions and outcomes in their lives and guide their future actions. Symbolic processes allow people not simply to react to events but rather to solve problems and generate new actions. Symbolic processes also foster communications with others (e.g., in person, virtually), which leads to further learning.

Self-regulation processes play a major role in social cognitive theory (Bandura, 1986; Usher and Schunk, 2018). People regulate their behaviors to conform to their internal standards and goals. Prior to beginning a task, they determine their goals and strategies to use. As they work on tasks, they assess their goal progress and decide whether to continue or alter their strategies. During breaks and when tasks are complete, they reflect on their experiences, seek to make sense of them, and determine their next steps. As they reflect on what they have done, the belief that they have learned strengthens their self-efficacy and motivates them to continue learning. The following sections explain these important processes in greater depth.

Vicarious processes

Functions of modeling

Bandura (1986) distinguished three functions of modeling: response facilitation, inhibition and disinhibition, and observational learning. *Response facilitation* refers to modeled actions that act as social prompts for observers to perform the same way. Response facilitation effects are common in everyday life. An individual walking down a street who encounters a group of people looking in a store window may stop and look in the window.

Response facilitation effects do not represent learning because people know how to perform the actions. The behaviors of others serve as cues for observers' actions. Response facilitation effects even can occur without conscious awareness (Chartrand and Bargh, 1999). People walking past a store clerk handing out coupons may mindlessly take one and then examine it.

Inhibition and disinhibition effects occur when models strengthen or weaken inhibitions to perform behaviors. Inhibition may occur when models are punished for their actions; disinhibition can result when models perform threatening or prohibited actions without negative consequences. Classroom misbehavior may be disinhibited when students observe other students misbehaving without being reprimanded by the teacher; a sudden reprimand may inhibit further misbehavior.

Like response facilitation, inhibition and disinhibition effects represent performance of previously learned behaviors, not new learning. A difference between these two categories is that response facilitation involves behaviors that are socially acceptable, but

inhibition and disinhibition typically involve actions that have moral or legal implications (e.g., breaking rules) or involve strong emotions (e.g., fears).

Observational learning

Observational learning through modeling occurs when observers act in ways that they had not learned to do prior to exposure to the models (Bandura, 1969). Observational learning has four component processes: attention, retention, production, and motivation.

Observational learning requires that observers attend to relevant features so that they can be perceived. Certain features of models and situations command better attention. Observers are more likely to attend to models who have status and credibility. Task features can affect attention, such as when teachers use bright colors, oversized features, and interactive materials. Attention also is affected by observers' beliefs about the functional value of the modeled behaviors. Modeled activities that observers believe are important and likely to lead to desirable outcomes enhance attention. Students' attention should be raised when teachers announce that the material they are about to cover will be in a test.

Retention involves cognitively organizing, rehearsing, coding, and transforming information for storage in memory. This aspect of observational learning has not been extensively investigated by social cognitive researchers. Cognitive information processing theorists and researchers have addressed this aspect in depth (Mayer, 2012).

Production involves translating cognitive conceptions of modeled actions into behaviors. Especially with complex behaviors, it often is the case that observers will learn only some features. Learners refine their skills through practice and feedback that may include additional modeling.

Motivation is important because observers are more apt to attend to, retain, and produce modeled actions that they believe are important. People are selective; they do not perform everything that they observe. Rather, they attempt to learn those actions they believe will lead to desirable outcomes and help them attain their goals, and they avoid those actions they believe will result in dissatisfying outcomes. People form expectations about the anticipated outcomes of actions based on their observations of models and other experiences. Their learning and performance of actions is based in part on these expectations.

Educational research

Researchers have substantiated the preceding points regarding observational learning. In school contexts, peers are important modeled influences on students (Schunk and Usher, 2019).

Researchers have investigated characteristics of peers that make them more credible models. Students are likely to attend to peers whom they believe are competent. Perceived similarity between models and observers can affect peer modeling (Schunk, 1987). Similarity in important ways serves as a source of information for determining behavioral appropriateness, forming outcome expectations, and assessing one's self-efficacy. Age similarity between model and observer is important for gauging behavioral appropriateness but less so for actual learning, which is enhanced better by models whom observers believe are competent. When competence and age similarity do not match (e.g., younger model more competent than a same-age model), children are swayed more by the competent model. Peers can be effective models when children hold self-doubts about their learning or performance capabilities. Viewing a similar peer successfully perform a task can raise observers' self-efficacy when they believe that if the model could learn, they can as well (Schunk, 1987).

Model gender can influence modeling by conveying information about task appropriateness. In general, observing a same-gender peer model perform without negative consequences conveys that the action is appropriate. Model gender is less important in learning academic skills and strategies (Schunk, 1987).

Researchers have explored the effects of exposing students to mastery and coping models (Schunk, 1987). Mastery models demonstrate desired performance from the outset. Coping models initially have difficulty learning skills, but through effort gradually improve their skills and eventually perform as well as mastery models. In a study exploring coping skills on an athletic task, 60 female high school students observed either a coping female model demonstrating dart-throwing techniques, a mastery model demonstrating flawless techniques, or no model (Kitsantas et al., 2000). The girls in the coping model condition surpassed skill acquisition over the females in the other two groups. In addition, learners who observed the coping models exhibited greater self-regulatory skills, intrinsic interest, and better learning. Children who have experienced previous difficulties learning may benefit more from observing coping models (Schunk and Hanson, 1985), presumably because children perceive themselves as more similar to coping models.

Researchers have found that it is helpful to incorporate modeled explanations into demonstrations such that models verbalize their thoughts and reasons for performing given actions. Meichenbaum and Goodman (1971) used cognitive modeling as part of a self-instructional program with impulsive children. Schunk (1981) compared the effects of cognitive modeling with those of didactic instruction on children's long-division self-efficacy and achievement. Children who lacked division skills received instruction and practice over sessions. Cognitive-modeling children observed an adult model explain and demonstrate division solution strategies while applying them to problems. Didactic-instruction children received written instructional material than explained and demonstrated the operations. Cognitive modeling led to greater division achievement and accuracy of perceived capabilities (i.e., self-efficacy corresponded more closely with actual skills).

Symbolic processes

Researchers have investigated the operation of symbolic processes on motivation. Symbolic processes include cognitions, beliefs, and mathematical/scientific notation. Some influential symbolic processes are self-efficacy, goals and self-evaluations of progress, outcome expectations, values, and social comparisons (Fig. 2).

Self-efficacy

In the model of reciprocal interactions, self-efficacy is a personal variable hypothesized to influence behaviors and environments and in turn be affected by them (Bandura, 1986, 1997). Students who feel efficacious about learning should engage in actions that improve learning, such as setting goals, using effective learning strategies, monitoring comprehension, evaluating goal progress, and creating effective environments for learning. In turn, self-efficacy is influenced by the outcomes of behaviors (e.g., goal progress, achievement) and by input from the environment (e.g., feedback from teachers, social comparisons with peers; Schunk and Usher, 2019).

People acquire information to assess their self-efficacy primarily from four sources: actual performances; observations of others (vicarious experiences); forms of social persuasion; and physiological indexes (Bandura, 1997). Actual performances constitute the most reliable information because they are tangible indicators of one's capabilities (Schunk and DiBenedetto, 2016). Successful performances raise self-efficacy whereas failures may lower it, although an occasional failure/success after several successes/failures should not have much impact.

Individuals acquire self-efficacy information vicariously through knowledge of how others perform (Bandura, 1997). Similarity to others is a cue for gauging one's self-efficacy (Schunk, 1987). Observing similar others succeed can raise observers' self-efficacy and motivate them to try the task; they are apt to believe that if others can do it, they can as well. But a boost in self-efficacy through vicarious experiences can be negated by subsequent failure. Persons who observe similar peers fail may believe they lack the competence to succeed, which can dissuade them from attempting the task.

Individuals also assess self-efficacy based on social persuasion from others (e.g., "I know you can do this;" Bandura, 1997). Social persuasions must be credible for people to believe that success is attainable. Although positive feedback can raise individuals' self-efficacy, the increase will not endure if they subsequently perform poorly (Schunk and DiBenedetto, 2016).

People acquire self-efficacy information from physiological and emotional indicators such as anxiety and stress (Bandura, 1997). Strong emotional reactions provide cues about anticipated success or failure. When people experience negative thoughts and fears about their capabilities (e.g., feeling nervous when thinking about speaking in front of a large group), those affective reactions can lower self-efficacy. When people notice that they are become less stressful (e.g., not as anxious while taking a test), they may experience higher self-efficacy for performing well.

Sources of self-efficacy information do not affect self-efficacy automatically (Bandura, 1997). Individuals interpret the results of events, and these interpretations provide the information on which judgments are based (Schunk and Usher, 2019). People weigh and combine information from various sources to form self-efficacy beliefs.

Self-efficacy is not the only influence on behavior. No amount of self-efficacy will produce a competent performance when students lack the skills to succeed. Students' values (perceptions of importance and utility of learning) also can affect behavior (Wigfield et al., 2016). Even students who feel highly efficacious about their science skills will not become science majors in college if they do not value a career as a scientist. Also important are outcome expectations (beliefs about the anticipated outcomes of one's actions; Bandura, 1997). Students typically engage in activities that they believe will result in positive outcomes and avoid actions that they believe may lead to negative outcomes. Assuming requisite skills and positive values and outcome expectations, self-efficacy is a key determinant of individuals' motivation, learning, self-regulation, and achievement (Schunk and DiBenedetto, 2016).

Fig. 2 Symbolic processes of motivation.

Self-efficacy can have diverse effects in achievement contexts (Bandura, 1997; Schunk and Usher, 2019). It can influence motivational outcomes such as choice of tasks, effort, persistence, and achievement. Individuals are apt to select tasks and activities at which they feel competent and avoid those at which they do not. Self-efficacy can affect how much effort people expend on an activity, how long they persist when they encounter difficulties, and their levels of learning and achievement. Students with high self-efficacy tend to set challenging goals, work diligently, persist in the face of failure, and recover their sense of self-efficacy after setbacks (Schunk and DiBenedetto, 2016). As discussed shortly, self-efficacy also can affect one's self-regulation activities (Usher and Schunk, 2018).

Goals and self-evaluations of progress

Goals are important symbolic processes that instigate and sustain actions. Goal commitment is critical because goals do not affect behavior without it (Locke and Latham, 2015). As people attempt to attain goals, they make progress judgments. Positive self-evaluations of progress strengthen self-efficacy, sustain motivation, and promote learning. Goals motivate people to expend effort and persist (Locke and Latham, 2015). A perceived discrepancy between performance and the goal may create dissatisfaction, which can raise effort and persistence and lead to better performance. Goals also help people attend to relevant task features, which can affect how people process information.

Goal properties

Goal properties of specificity, proximity, and difficulty affect motivation and learning (Zimmerman et al., 2015). Goals that include specific performance standards are more likely to lead to self-evaluations of progress and enhance motivation and learning than are general goals (e.g., "Do your best," Bandura, 1986). Specific goals indicate the amount of effort needed to succeed and evaluating progress toward specific goals is straightforward. Goals also differ by how far they project into the future. Proximal, short-term goals enhance motivation and learning better than do distant, long-term goals, because it is easier to determine progress toward goals that are closer at hand (Bandura and Schunk, 1981).

Difficulty, or the level of task proficiency required as assessed against a standard, can determine the amount of effort that people expend. Goals perceived as difficult but attainable are the best motivators. Goals viewed as too difficult do not motivate because people hold low self-efficacy for attaining them. Although people may feel efficacious for attaining goals perceived as very easy, these goals also may not motivate because people often procrastinate.

Learning and performance goals. Another distinction is between learning and performance goals. A *learning goal* refers to what knowledge, behavior, skill, or strategy students are to acquire; a *performance goal* refers to what task students are to complete. These goals can have differential effects on achievement behaviors (Anderman and Wolters, 2006). Learning goals focus students' attention on processes and strategies that help them acquire competence and improve their skills. The task focus motivates behavior and sustains attention on critical task aspects. Students who pursue a learning goal are apt to feel efficacious for attaining it and be motivated to expend effort, persist, and use effective learning strategies. Self-efficacy is substantiated as they work on the task and make positive self-evaluations of progress (Zimmerman et al., 2015).

In contrast, performance goals focus attention on completing tasks. They may not highlight the importance of the processes and strategies underlying task completion or raise self-efficacy for learning. Learners may not compare their present and past performances to determine progress. Performance goals can lead to social comparisons with others. These comparisons can lower self-efficacy among students who experience learning difficulties, which adversely affects motivation and learning (Anderman and Wolters, 2006).

Outcome expectations

Outcome expectations (e.g., "If I study hard, I should do well on the test.") are beliefs about the expected outcomes of actions. People form expectations based on personal experiences and observations of models (Bandura, 1986). Individuals act in ways they believe they will be successful and attend to models whom they believe will teach them valued skills. Outcome expectations can sustain goal-directed actions over lengthy periods when people believe their actions will eventually produce desired outcomes.

Self-efficacious students typically believe that their actions will result in positive outcomes, which keeps them motivated even when progress occurs slowly. Conversely, those whose self-efficacy is weaker may, when they encounter difficulties, work halfheartedly or quit. This situation can be demoralizing; students may believe that positive outcomes will result but lack the self-efficacy to continue. For example, they may believe that if they studied effectively they would do well on the test, but may doubt their self-efficacy to study effectively.

Values

Value refers to the perceived importance or usefulness of learning. Bandura's social cognitive theory predicts that actions reflect one's values (Bandura, 1986). Individuals strive to bring about what they desire and to avoid outcomes that are inconsistent with their values. They are motivated to learn when they deem that learning important. Students who value high grades are likely to engage in activities that should lead to high grades, such as attending class, keeping up with reading, turning in assignments on time, and studying for exams.

Achievement motivation researchers have shown that expectancies for success—a variable similar to self-efficacy—and values affect motivation (Wigfield et al., 2016). Expectancies predict achievement and values are better predictors of choices, such as intentions to take courses and enrollment in those courses (Wigfield et al., 2016).

Social comparisons

Social comparison refers to comparing ourselves with others (Wheeler and Suls, 2005). Although people often compare their performances with objective standards, they also evaluate their capabilities by comparing themselves with others. Social comparisons indicating that one is more competent than others can raise self-efficacy and motivation; social comparisons that result in negative self-evaluations can diminish these outcomes.

The most accurate self-evaluations arise from comparisons with others whom people believe are similar to themselves in the ability or characteristic being evaluated. The more alike observers are to models, the greater the probability that similar actions by observers will produce comparable results (Schunk, 1987). Model-observer perceived similarity in competence can improve learning (Braaksma et al., 2002). Observing similar others succeed can raise observers' self-efficacy and motivation. Similarity seems especially influential with persons who have experienced difficulties and possess self-doubts about performing well (Schunk and Usher, 2019).

Educational research

Researchers have explored the operation of social cognitive variables (e.g., self-efficacy, goals, social models) in various domains (e.g., education, business, health, computer applications). Participants in research studies have differed in age, developmental level (e.g., PreK-12, postsecondary), ethnicity, and abilities (e.g., regular, remedial, gifted) (DiBenedetto and Schunk, 2018). This research literature shows that self-efficacy influences motivation, achievement, and self-regulation, and in turn is affected by achievement outcomes (Bandura, 1997; Pajares, 1997; Schunk and DiBenedetto, 2016; Schunk and Usher, 2019).

Self-efficacy is especially influential on academic outcomes and performance accomplishments are the most reliable source as they provide evidence of what students can accomplish (Schunk and DiBenedetto, 2020). Self-efficacy correlates with motivation, learning, and achievement (Schunk and DiBenedetto, 2016). Both correlational and empirical research have demonstrated the effect of self-efficacy on academic self-regulation and achievement (Schunk and DiBenedetto, 2020). Cattellino et al. (2019) examined the mediation effects of self-efficacy on adolescent's self-regulation and performance in relation to the severity of parental and school rules on 804 Italian students. Students were administered a survey at the beginning of the school year, then again six months later. Path analysis revealed self-efficacy mediated the relationship between perceived severity of parental and school rules and school achievement six months after the initial survey was administered.

In another recent study, 273 twelfth-grade students' reading self-efficacy beliefs were collected using two instruments, one focused on reading self-efficacy and the other on reading comprehension (Dona et al., 2019). Findings showed a significant correlation between self-efficacy and performance. DiBenedetto and Bembenu (2013) examined changes in science self-efficacy for 113 college students over a semester in which students were enrolled in intermediate level science courses. Findings revealed self-efficacy beliefs at the end of the semester declined and yet were more closely related to final term averages than they were at the start of the semester, suggesting that students' beliefs about their performance became better calibrated as the semester progressed.

Experimental research studies have shown that instructional and social/environmental processes that convey information to students that they are becoming more competent raise self-efficacy, motivation, and achievement (Schunk and DiBenedetto, 2020). Falco and Summers (2019) conducted an intervention study incorporating the four sources of self-efficacy on high school girls' STEM (science, technology, engineering, mathematics) career self-efficacy beliefs. Eighty-eight ethnically diverse high school girls were split into intervention and control groups. The intervention group received nine 50-min counseling sessions targeted at building students' self-efficacy for making intentional career decisions and for building self-efficacy for careers in STEM. Results showed positive moderate-to-large effect sizes for the impact of the intervention on both students' career decision making self-efficacy and self-efficacy for careers in STEM.

Ramdass and Zimmerman (2011) examined the influence of modeling and social feedback on 76 sixth and seventh grade students' self-efficacy and mathematical achievement. Students were randomly assigned to one of four conditions: coping models with and without social feedback; and mastery models with and without social feedback. Findings revealed that students in the coping model conditions surpassed those in the mastery model conditions on the posttests and their self-efficacy was better associated with higher mathematics performance. These findings are similar to those cited earlier in the athletic study conducted by Kitasantas et al. (2000).

Self-regulation

An important expansion of social cognitive theory is into self-regulation (Usher and Schunk, 2018). This section discusses phases of self-regulation, the social-to-self progression in learning self-regulatory skills, and educational research.

Phases of self-regulation

Self-regulation refers to self-generated thoughts, feelings, and actions, which learners use to attain their goals (Zimmerman, 2000; Zimmerman and Schunk, 2004). Reciprocal interactions are evident in self-regulation. While working on tasks, learners may self-regulate personal factors, such as by setting goals, monitoring and evaluating progress, assessing self-efficacy for continued learning, and creating a positive emotional climate. They may exert behavioral self-regulation by employing learning strategies, verbalizing aloud or covertly steps to follow, and self-recording progress. They exert social/environmental control when they create productive work environments and seek assistance when needed. In turn, the result of their self-regulation affects self-efficacy, goals, strategy use, and other self-regulatory behaviors (Usher and Schunk, 2018).

Zimmerman (2000) developed a social cognitive cyclical model of self-regulation that includes reciprocal interactions and the changing nature of self-regulation. This model includes forethought, performance, and self-reflection phases. The forethought phase precedes learners' actions and includes processes that set the stage, such as setting goals and assessing self-efficacy for learning. During the performance phase, learners implement strategies and control their attention to focus on the learning context. The self-reflection phase, which occurs during breaks and after task completion, includes individuals' responses to their efforts, such as assessments of their learning progress and the effectiveness of their strategies.

Students' self-evaluations are critical and have cognitive, behavioral, and motivational effects. Especially important are learners' self-evaluations of their learning progress. Positive self-evaluations that they are making goal progress lead students to experience self-efficacy for continued learning and motivate them to continue to work diligently. Low self-evaluations of progress will not necessarily lower self-efficacy and motivation if learners believe that they can make better progress. Such learners may alter their self-regulatory processes by working harder, persisting longer, adopting what they believe is a better strategy, or seeking help from teachers, parents, coaches, or peers (Zimmerman, 2000). Research supports the use of the processes in the three phases of self-regulated learning among high performing students and demonstrates the processes to be highly correlated with one another (DiBenedetto and Zimmerman, 2010).

Social-to-self progression

Learners benefit from instruction on self-regulatory strategies, but it is critical that these strategies become *internalized*, or integrated into learners' self-regulatory systems. This internalization process occurs in a social-to-self progression comprising observation, emulation, self-control, and self-regulation (Fig. 3; Zimmerman and Schunk, 2004). Initially, learners acquire the rudiments of a skill by observing a model's performance. During emulation, students learn to duplicate a model's actions on the task, which involves emulating the model's general behavioral pattern or style of functioning.

At the self-control level, learners practice the skill apart from the model while monitoring their practice using cognitive and behavioral strategies. The fourth level (self-regulation) requires learners to make adjustments based on their outcomes. Learners can perform the skill with minimal self-monitoring because many elements have become internalized and may return to any of the levels as needed.

Self-regulatory skills can be learned without following these steps. For example, learners who have developed some self-regulatory skills may be able to refine new skills as they independently practice them. This progression, however, offers a sound basis for instruction and especially for students in the early stages of learning how to self-regulate their academic performances (Zimmerman, 2000).

A self-regulated framework

White and DiBenedetto (2015) presented an integrated framework whereby learners engage in the three phases of self-regulated learning within the four levels of self-regulatory competency (see Fig. 4). Pacing is critical in each of the phases as, initially, teachers are controlling the learning by modeling then gradually giving the students full control. As students begin to internalize self-efficacy

Fig. 3 Levels of self-regulatory competency.

Fig. 4 Integrated framework: The three phases of self-regulated learning and the levels of self-regulatory competency.

and self-regulatory skills, they move from phase to phase within each level acquiring more independence. For example, during the *observation level* a fourth-grade teacher through cognitive modeling may verbalize how she would prepare for an upcoming mathematics exam by doing ten practice problems from the workbook (forethought phase: strategic planning). She models strategy use by completing the math practice problems and engages students to work on these practice problems with her (performance phase). The teacher then models evaluating her performance by making attributions and checking her progress on strategy use (self-reflection phase). The framework could be implemented as a form of instructional support at each of the four levels (observation, emulation, self-control, and self-regulation) to promote independent self-regulated learners (Bell and Pape, 2014). While research has been conducted on the three phases of self-regulated learning and the four levels of self-regulatory competency, research is needed to demonstrate the potency of this integrated framework.

Educational research

Researchers have identified the links between self-efficacy and self-regulation. In line with theoretical predictions, self-efficacy can influence such self-regulatory processes as goal setting, self-monitoring, self-evaluation, and strategy use (Usher and Schunk, 2018; Zimmerman, 2000). Self-efficacious students set challenging goals, persist, use effective learning strategies, and monitor their performances. These actions enhance self-efficacy and motivation for continued learning.

Self-evaluations of capabilities affect self-regulation and achievement (Schunk and Ertmer, 2000). Research by Schunk and Ertmer (1999) using college students showed that when opportunities for self-evaluation were infrequent, learning goals promoted achievement outcomes better than performance goals. However, when self-evaluation opportunities occurred regularly during instruction, the college self-evaluation the benefits of learning goals and led to enhanced self-efficacy and achievement regardless of learners' goals.

Researchers also have obtained support for the social-to-self progression. In teaching writing skills to college students, Zimmerman and Kitsantas (2002) found benefits when students observed models before they attempted performance. Other research has obtained support for the sequencing of the third and fourth levels (Zimmerman and Kitsantas, 1999). In this study, high school students initially received instruction and practice on a writing strategy (levels one and two). They then received a process goal (learning a revision strategy—level three), an outcome goal (decreasing the number of words in the revision—level four), or a process goal followed by an outcome goal. Shifting the goal resulted in better self-regulation than focusing exclusively on one type of goal.

Contributions

Although self-regulation has been addressed by other theoretical perspectives including behavioral, information processing, constructivist, and socio-cultural theories. There are noteworthy features of social cognitive theory. One is its emphasis on observational (vicarious) learning. This is especially evident in the social-to-self progression model. Vicarious learning speeds up the learning process over what would be possible if learners had to practice every action. Through observation of models, learners can acquire a sense of self-efficacy for learning that enhances their motivation and skill development.

Social cognitive theory also emphasizes self-efficacy. Learners initially may hold a sense of self-efficacy for learning, which motivates them to attend to models and practice skills. As they perceive that they are becoming more skillful and performing better, their self-efficacy for learning is strengthened, which leads to motivation for further improvement.

Finally, with its emphasis on reciprocal interactions between personal, behavioral, and social/environmental factors, social cognitive theory underscores the dynamic and changing nature self-regulation. Learners are proactive and seek ways to improve their skills, which can instate a sense of agency that they can exert much control over their academic learning.

Educational implications

Social cognitive theory and research suggest ways to improve teaching and learning through models, goals and self-evaluations of progress, self-efficacy for learning, and self-regulation.

Models

Instructional models inform and motivate learners. When they observe live or virtual models explain and demonstrate skills and strategies, learners acquire information about correct sequences of actions. When learners believe they understand what is being demonstrated, they likely will be motivated to demonstrate it. Peer models can be especially effective motivators. The perception of similarity raises observers' self-efficacy and motivates them to perform.

Students who often experience learning difficulties may benefit from observing peer coping models, that is, models who initially encounter difficulty learning but through effort, persistence, and correct strategy use, gradually improve their skills. Observers may perceive themselves as more similar in competence to coping models than to peer mastery models who demonstrate faultless performance from the start.

Goals and self-evaluations of progress

An effective means of developing learners' skills, self-efficacy, and motivation is for them to set learning goals and evaluate their learning progress. Goals that are close at hand, specific, and moderately difficult, are strong motivators. With long-term tasks (e.g., writing a paper), teachers can help students break the task into a series of subgoals (e.g., identify a topic, do research, write the first draft).

Students' learning and motivation benefit when they believe they are making progress in learning. Gauging progress is difficult for some tasks (e.g., becoming a better reader or writer). It is easier to gauge progress against subgoals than longer-term objectives. Learners can assess their progress in various ways such as by self-recording what aspects of the task they completed and judging their self-efficacy for performing subgoals. The perception of learning progress raises self-efficacy and motivation.

Self-efficacy for learning

For learners who lack skills, self-efficacy for performing them is apt to be low and thus not a motivator for students who lack the skills. For these students, self-efficacy for learning is a better motivator.

But if learners do not understand what is required to learn (i.e., what component skills are needed), they may judge self-efficacy for learning unrealistically low. In this case, teachers can point out what they have learned and how the new learning will draw on what they already know. Learners will feel efficacious about learning mathematical division when they understand that division requires estimating, subtracting, and multiplying skills they possess. Learners who engage in a task with a sense of self-efficacy for learning and who perceive that they are making learning progress will be motivated to continue.

Self-regulation

Social cognitive theory underscores learners becoming self-regulated. Self-regulatory skills such as strategy use and self-monitoring can be modeled. Setting goals and evaluating progress are self-regulatory processes that keep learners task-focused and maintain motivation. Having students evaluate self-efficacy at the outset of a task and during periods of self-reflection can convey that they are making progress, which strengthens self-efficacy and motivation.

DiBenedetto and Zimmerman (2010) showed that students who are self-regulated outperform students who engage in less self-regulatory processes. The cyclical nature of self-regulation suggests that teachers may need to assist learners to set new goals as they attain their current ones. Attaining goals denotes progress, especially when the goals represent subgoals in a larger task. Working on the next subgoal may require learning new skills, which teachers can facilitate through modeling.

Future research directions

There are several issues that merit future research. Discussed in this section are methodological refinements, cross-cultural relevance, and integration with technology.

Methodological refinements

Motivational variables stressed by social cognitive theory (e.g., outcome expectations, self-efficacy) are not static but can change quickly and frequently, but often motivation variables are assessed in a static fashion such as by using questionnaires that require aggregated and retrospective judgments. These measures capture changes between two time points but not changes that occur during task engagement.

Increasingly researchers are using real-time measures. For example, microanalytic methods collect assessments before, during, and after task engagement. Think-aloud protocols capture participants' thoughts as they engage in learning. Interviews ask participants about their thoughts at various times. Written diaries ask learners to record their thoughts as they work on tasks. With technology, traces show learners' progress through a learning episode. These and other types of assessments capture dynamic changes in motivation.

Because a variable such as self-efficacy can change rapidly, fine-grained measures are preferable because they show changes over time. Then researchers can map these changes against changes in instructional and social conditions, which will suggest future research directions and how to structure environments to promote beneficial motivation outcomes.

Cross-cultural relevance

Most social cognitive research has been conducted in Western societies, but this situation is changing as researchers are testing principles of social cognitive theory globally. The topics of self-efficacy and self-regulation have much international appeal. And cross-cultural research has yielded differences (McInerney, 2008). Klassen (2004) found that, compared with learners in collectivist cultures, those in individualistic (Western) cultures tend to judge self-efficacy higher. Interestingly, the alignment between students' self-efficacy and demonstrated skills is better for those in collectivist cultures. This is an important criterion. Students who overestimate their self-efficacy may attempt tasks beyond their means and perform poorly. Those who underestimate may be reluctant to engage in tasks and thereby preclude opportunities for learning (DiBenedetto and Schunk, 2018). These results suggest that collectivist cultures may promote modest self-efficacy judgments and that in some cultures collective self-efficacy (self-efficacy of what a group can accomplish) may better predict learning outcomes than will individual self-efficacy.

Overall, the principles espoused by social cognitive theory have shown themselves to be cross-culturally relevant. International researchers will continue to refine and test ideas in diverse cultural contexts.

Integration with technology

Social cognitive theory was largely developed prior to the advent of technological advances. Most research has been done in face-to-face settings. This does not mean that the theory needs major revisions because the principles are intended to be generic and apply across different contexts. But the role of technology requires some theoretical adaptations.

In particular, social cognitive research is needed with social media. These media offer ways for learners to have social contact with others, and we know little about how such interactions may influence self-efficacy and other variables. Learning from others is a source of self-efficacy information, and this should be true regardless of whether the interactions are live or virtual. Social media fit well with a theory with the "social" in its title.

Such research has implications for teaching and learning. There are educational uses using technologies such as Facebook and Zoom. How might these and other forms of media be used to help students set goals, monitor progress, assess self-efficacy for learning, and the like? How might instruction be designed to incorporate social media that take self-efficacy of learning and teachers into account? Research is needed to expand the generality of the theory beyond its original formulation.

Conclusion

Social cognitive theory is a general theory that stresses learning from the social environment. From its early focus on observational learning through modeling, social cognitive theory has expanded in scope to address such processes as motivation and self-regulation.

Bandura's social cognitive theory postulates reciprocal interactions among personal, behavioral, and social/environmental factors. Researchers in this tradition have investigated the operation of vicarious, symbolic, and self-regulatory processes, in the various ways that individuals interact with their environments and one another.

A key point is that persons seek to develop a sense of agency for being able to exert a large degree of control over important events in their lives. Among the influential variables affecting one's sense of agency are self-efficacy, outcome expectations, goals, and self-

evaluations of progress. We can expect further refinements in the theory as researchers apply this agentic perspective to human functioning in diverse areas in education and other domains.

Intermental Intramental psychological functions

Introduction

Humans have an incredible talent for learning. We are helpless at birth and completely dependent on external support for all our needs. During a period of a few years, we learn to walk, run and master our body, to play, talk and interact with other people, and a wide range of physical, intellectual and communicative skills. We are biological beings, primates, but our developmental trajectories during ontogeny differ, in intriguing ways, from those of our next of kin in the evolutionary sense. One of the features that stands out as particular about human learning and development during ontogeny is our flexibility. As a species, we are able to adapt to considerable variations in the cultural, material and societal conditions of the environment. Even though the capacity to learn a language is general, the language(s) we learn in infancy are those that are used in our immediate environment. A child in a monolingual family will learn the language of the parents, while a child growing up in a bi- or multilingual setting may learn two or even more languages, if the parents/guardians decide to expose the child to their respective mother tongues. Also, the material conditions in which children grow up testify to the flexibility of developmental trajectories. The material surroundings of children growing up in a megacity, beginning preschool/school at an early age and, in many cases, attending formal education well into their 20s, are different from those of a child growing up in a nomadic community in the desert. And, these differences will have consequences for socialization and what children learn and know. A rather dramatic illustration of the impact of cultural habits on children's developmental trajectories in contemporary society is the role that the Internet and digital tools currently play. In many societies, children as young as one or two years of age spend time on the Internet every day. They engage in practices such as watching video clips, listening to music, gaming and communicating with friends and relatives (Statens medieråd, 2019; UNICEF, 2019). These latter developments represent a significant change in the daily practices of children and young people that were inconceivable a few decades ago, and they are consequential for their learning trajectories and knowledge of the world.

However, and to add to the issue of flexibility, learning should not be seen as an individual activity only, as is commonly done. Throughout history, we have seen many changes in the living conditions of humans brought about by new technologies, inventions and insights. The wheel, the plow, the bow and arrow, writing, number systems, book printing, radio, television, cars, computers and an almost endless number of inventions and discoveries have changed our lifestyles, our mental and physical capacities and our knowledge of the world. This development of new technologies—artifacts—is an important outcome of the human capacity to learn. We are able to convert many of our insights into artifacts, which, in turn, transform how we live and learn.

Thus, we do not merely adapt to external conditions, we transform them. We live in a world that is designed—materially as well as intellectually. The transformation of the physical environment began with the development of material culture that goes back a long time before modern humans—*Homo Sapiens*—appeared. The oldest artifacts date back well over three million years (Harmand et al., 2015), while *Homo Sapiens* appeared as late as a few hundred thousand years ago (depending on definitions, see Callaway, 2017). So, learning is also about how collectives, societies and institutions learn and develop by continuously incorporating experiences, insights and technologies into the organization of daily practices.

This short summary provides a picture of the complexity and multilayered nature of the phenomenon of learning. In one sense, we are biological beings with limitation in terms of our physical strength and cognitive capacities. In another sense, we are tool-makers with infinite capacities for collaborating, inventing and expanding our knowledge and skills in ways in which no other species come close to. We build institutions and societies by accumulating knowledge—intellectual and material—over time; each new generation builds on the achievements of those that have gone before (Caldwell and Millen, 2008). This capacity for designing environments, in turn, implies that the conditions of learning and development continuously change. Societies become more diverse when knowledge expands. In the history of research on learning and development, there is a tension between conceptualizing learning as localized within individuals (in minds, brains, perceptual systems) versus conceiving it as processes that are embedded in social practices and in the co-ordination between people and between people and technologies and other external resources. This tension between perspectives divides research on learning (and development) in interesting ways.

The sociocultural perspective on learning

The sociocultural perspective, also referred to as the sociohistorical or cultural-historical research tradition, is best understood as a perspective rather than as a single and unified theory. There are important conceptual and methodological implications of adopting such a perspective in research and when designing educational activities, but all the research that is currently conducted under this conceptual umbrella in different fields cannot be reduced to one single theory.

What we now refer to as the sociocultural perspective originates in the work of the Russian psychologist Lev S. Vygotsky (1896–1934). As a student at the University of Moscow, Vygotsky had broad intellectual interests. His first degree was in law (1917), but his intellectual curiosity took him in other areas including linguistics, literature and philosophy. His dissertation, *The psychology of art* (Vygotsky, 1971), was published in 1925, but he never defended it owing to health problems (which continued to torment him throughout his short life). This is not the place to go into the history of the Vygotskian intellectual legacy (cf., e.g. Kozulin, 1986a,b), but it is interesting to note that his work did not receive much attention among Western scholars until the 1960s and 1970s. During the period of de-Stalinization in the Soviet Union, contacts between East and West became more frequent and academic exchange became possible.

In 1962, the first version of Vygotsky's influential work, *Thought and language*, appeared in a highly abridged version and with a foreword by Jerome Bruner (1915–2016). Later, extended editions appeared in 1986 (edited by A. Kozulin) and in 1987 as part of one of the volumes of Vygotsky's collected works. In the latter case, the title was changed to *Thinking and Speech*, and this reformulation is significant. Today, most scholars would agree that this translation better captures the interactional, processual, and communicative perspective on language and thinking that Vygotsky articulated. This issue of how to translate Vygotsky's concepts into English, in itself, has attracted intense scholarly debates over the past decades. Many researchers argue that the terms chosen in English in part misrepresent or even distort Vygotsky's ideas. There is an extensive literature on the reception and interpretation of Vygotsky's work by Western scholars (cf., e.g. van der Veer and Valsiner, 1991; Veraksa and Sheridan, 2018; Yasnitsky, 2012), which testifies to the significance of his achievements for contemporary research on learning, development and schooling. As is the case with many great scholars, his writings are inspiring and suggestive, and open to different interpretations and emphases.

When discussing the origins of the sociocultural perspective, the contributions by Alexander Luria (1902–1977) and Aleksei N. Leontiev (1903–1979) should be recognized. Luria was a young scholar at the Institute of Psychology in Moscow when Vygotsky joined during the 1920s. Luria was studying the correlates between psychoanalytical concepts and processes and more “objective” psychological observations. Luria was a truly interdisciplinary scholar and he finished a medical degree after the death of Vygotsky. He is now referred to as one of the founders of modern neuropsychology through his research on how brain injuries impact psychological functions (such as memory), issues that he studied in his capacity as clinician and researcher in hospital care of wounded soldiers during and after World War II. Leontiev is known as the founder of Activity Theory, a theoretical perspective that gained prominence in the Soviet Union during the 1970s and that grew out of Vygotskian ideas. But there is an interesting debate on the tensions between Activity theory and some of the basic Vygotskian assumptions (cf., e.g. Kozulin, 1986b). In the literature, Vygotsky, Luria and Leontiev are often referred to as the founding “troika” of the sociocultural perspective.

Learning and mediation

Vygotsky was a developmental psychologist with interests in language, learning, esthetic development, and education. One way of understanding the intellectual origins of the sociocultural perspective is to start by considering what Vygotsky saw as shortcomings in the psychology of his time. He repeatedly talked about psychology as in a state of “crisis”, as a result of a lack of proper theoretical and methodological foundations (cf. Kozulin, 1999, p. 73ff; Vygotsky, 1997). One central element of his critique was directed toward the dominant stimulus-response theorizing of this time, that is, what in the West was referred to as behaviorism and in the Russian context as reflexology (which preceded the behaviorist movement). Vygotsky's critique, shared with his contemporaries John Dewey (1859–1952) and Jean Piaget (1896–1980), is that the assumption that learning and development can be understood through stimulus-response connections and reinforcement in the Pavlovian sense is mistaken and far too simplistic. There are many elements of what people learn that cannot be explained in this way.

In this context, Vygotsky makes a distinction between what he refers to as “lower” and “higher psychological (or mental) processes.” Initially, this choice of terminology may seem a bit strange, but what is meant is that some of our behaviors are straightforward reactions and responses to stimuli in the environment, while others are of a very different nature. We have genetically determined, natural reactions such as sucking and closing our eyes when exposed to light. In modern parlance, these reactions are hardwired into us, and they require no thinking or conscious reflection. These are the lower psychological processes or functions that may be successfully studied by means of stimulus-response psychology in the Pavlovian, behaviorist tradition.

Higher psychological functions, on the other hand, are different (Podolskiy, 2012). They involve our capacities to think, to use signs and language, to act creatively and to control our own thinking and our behaviors. Such functions are unique to humans, and they emerge from social interaction, where we encounter and learn to use signs and categorize the world around us (Vygotsky, 1977). The concept of *sign*, thus, is central to Vygotsky’s thinking. In *Mind in society* (Vygotsky, 1978, p. 40) he uses a simple triangle to explain the role of signs for human thinking, cognitive development and communication more generally.

The idea here is that, in the stimulus-response connection (and in lower psychological processes), there is an immediate and direct link between a stimulus and the reaction (indicated by the upper line). However, only a very limited proportion of our behaviors builds on such direct connections. Instead, a peculiar feature of human thinking is that our relation to the world is *mediated* by signs. When we see something, our thinking involves the use of signs by means of which we perceive and categorize what we encounter. To take an example, when I look out my window, I admire the beautiful roses in my neighbor’s garden. I can see that they are very different in color (pink, red, yellow etc.), shape (some big, others small) and I know that the seasons when they blossom are different. Still, I see that they are roses. Why do I do this? The answer is that my perception is mediated by a sign that even an amateur is familiar with—I know what a rose looks like. In sociocultural terms, I have access to a term/sign that I use in a variety of actions: it mediates my seeing, remembering, communicating. Thus, my thinking is not a direct response to colors or shapes of the plants I observe, it is mediated by conceptual knowledge. And another important point is that this knowledge of what a rose is, is not my own invention, it is a concept that has a long history and that I have learned to use through social interaction. Thus, my knowledge is sociohistorical (has been used for a long period), social (shared with others) and individual (known by me).

Human thinking through sign systems thus implies that our thinking, metaphorically speaking, makes a detour via shared conceptual systems as indicated by the X in the triangle in Fig. 1. We perceive, talk and think about roses, clouds, cars, mammals and everything else that is around us through linguistic categories. And, much of our knowledge is conceptual or discursive to use a more recent term. We learn about the world largely by appropriating signs and discourses.

Thus, the sociocultural and neo-Vygotskian metaphor for learning is *appropriation* (Vygotsky referred to this as internalization but this term has some unfortunate connotations as has been pointed out by Rogoff, 1990, and others). Appropriation takes place through social interaction. Children (and adults) encounter concepts and knowledge in socially shared activities as “intermental (or interpersonal) categories”, and through this exposure, they may appropriate them as “intramental (intrapersonal) categories”, that is, as tools they can use for thinking. Thus, language (and sign systems) operate both between people and within them; “interpersonal use” leads to “intrapersonal use” (Vygotsky, 1978, p. 27ff). When I talk to my neighbor about her interest in roses, she can give detailed explanations of all the kinds of roses that exist (there are thousands, if you include hybrids), where they come from, what soil they require, how to cultivate them etc. Thus, she has appropriated a range of conceptual distinctions and physical knowledge that I am not familiar with but, if I were to spend time with her in her gardening, I could very well appropriate some of the relevant conceptual and physical skills. By engaging in joint activities and communication, the intermental categories that she uses when we talk may become intramental categories for me as a less knowledgeable partner in this particular interactional partnership (Wertsch, 1991). This is a central mechanism for communicating knowledge.

An important consequence of the capacity to use signs, emphasized by Vygotsky, is that they allow us to regulate our own actions and behaviors. Thus, concepts/signs are turned inwards in the sense that they allow us to remember, analyze and perform other activities that require sophisticated planning, logical reasoning and considerations of alternatives. Vygotsky (1978, p. 57) argues that the appropriation of “cultural forms of behavior involves the reconstruction of psychological activity on the basis of sign operations.” Through involvement in social interaction, children eventually “succeed in applying a social attitude to themselves” (p. 27) and consider their own actions and decisions (“I must be careful”, “I mustn’t not forget” etc.) in concrete situations.

Fig. 1 Signs and mediation.

Tool mediated action

Language and sign systems, thus, are tools for thinking. The concept of tool is central to the Marxist thinking that Vygotsky was influenced by. We can think of language and other sign systems (writing, number systems and others) as in some sense analogous to physical tools that we use in activities such as gardening, digging and fishing. They are also integrated in social activities. The sophistication of the conceptual knowledge of my neighbor implies that she knows a lot about roses, their various appearances and their history, but part of her knowledge allows her to perform all the physical activities and use the full range of tools that are associated with cultivating roses. With physical, or technical, tools we carry out physical work, while conceptual tools are tools of the mind that allow us to think, communicate and plan our actions; in concrete actions they are interrelated.

Thus, in the sociocultural tradition, human actions, including thinking and physical action, are seen as tool mediated. Whatever we do, we use tools, and these tools have a social origin and sometimes a long history (sociogenesis). Vygotsky argues that language has a special status, it is the “tool of tools” and basic to human cognitive and intellectual functions. It is the technology of the intellect and an element of most of what we do. [Luria \(1981\)](#) points out that through the use of language as a sign system, we have a dual or double relationship to the world and what we do: we live *in* the world by performing complex activities (including talking), but we can also communicate *about* the world and what we do. We can discuss with others, borrow their insights and experiences, and engage in hypothetical thinking: what if we would do this instead of that? What would the consequences be? Again, this is something that is unique to humans.

The analogy between conceptual and physical tools should not make us think of them as totally separate. Rather, they coexist and presuppose each other. When I use a ruler or a scale to measure length and weight, the physical artifacts incorporate signs (numbers, classifications such as centimeters, inches, pounds), and the user orients to these signs while using them. Without the signs, artifacts of this kind would be useless or at least less helpful. As an alternative to using an ontology that separates intellectual (mental) and physical (material) tools, we may see them as cultural tools: human inventions that are socio-material and by means of which we interact with and transform our world.

Cultural tools extend human capacities far beyond the limitations of the resources provided to us by nature, as it were. With an axe, we can chop down a tree, and with a chain saw this is even quicker and requires less energy and strength. Analogously, with some knowledge of elementary geometry and a suitable measuring device, we can easily calculate the size of a room or a lawn when planning some concrete activity. Through history, there have been many inventions that have radically changed human intellectual capacities, our daily practices, and the societies we live in. One of the most obvious examples is the invention of writing about 5000–6000 years ago (depending on definition, see [Schmandt-Besserat, 1996](#)). Written language transformed how societies and individuals store and access information. The human memory at one level is quite limited. We have a limited attention span and we often forget and distort information. When writing and texts were introduced, the capacity for remembering was transformed for individuals as well as for societies. By documenting information and discourses, such as those used in science, religion, business and elsewhere, in texts, the human capacity for remembering and for conceptual thinking was radically transformed. In fact, when remembering is supported by texts, there are no absolute limits to how much information we can have access to. New insights and stories can always be documented and communicated, and this is precisely what we have seen over the millennia. This is a good illustration of higher psychological processes; no animal, no matter how sophisticated it is, will take a pencil and jot down something that has to be remembered.

New cultural tools thus imply a new division of labor between our minds, hands and artifacts. When new cultural tools are introduced and appropriated in society, our thinking, problem-solving, remembering, and other intellectual functions may change. Paper and pencil make it easier to multiply two four-digit number with two decimals than if are to perform these operations through mental arithmetic. An electronic calculator again changes the ways in which we perform calculations in daily practices. Using such a tool, multiplying large numbers with decimals is not more difficult than multiplying 2×2 for most people ([Säljö et al., 2006](#)). What happens in tool mediation is thus that some part of the cognitive process is achieved in collaboration with the tool. In the case of multiplying large numbers, the problem when not using paper and pencil or a calculator is that the calculation requires that we keep a lot of information in mind, that is, our short-term remembering is heavily taxed. Even if we know the principles of how to perform such calculations through mental arithmetic, it will be difficult for most people to manage this when the numbers are big and involve decimals ([Säljö et al., 2006](#)). With the tool (nowadays available on the mobile phone), the problem becomes almost trivial.

In a short paper, originally a lecture, [Vygotsky \(1981\)](#) makes a brief comment which illustrates the differences between traditional cognitivist and sociocultural perspectives on cognition and learning. In the former case, cognitive processes are seen as inherent to the mind/brain, while in the sociocultural perspective cognitive processes rely on cultural tools and are transformed when new cultural tools appear. Vygotsky thus argues that a new cultural tool “abolishes and makes unnecessary a number of natural processes, whose work is accomplished by the tool” (p. 139). The “natural processes” of remembering, calculating or whatever, will be transformed as the processing is accomplished in collaboration with tools. This is why, in a sociocultural and cultural-historical perspective, human thinking changes as the artifacts and technologies of the societies in which people grow up undergo change. To remember by using texts or databases, and to navigate at sea by using maps or GPS navigators, imply very different types of cognitive work in comparison to how such activities were handled earlier in history when such cultural tools were not available. Many examples of such changes in remembering, access to information and problem-solving can be observed as digitization spreads into the cognitive fabric of societies. Phone numbers do not have to be remembered any longer, search engines help us find what we look for and a specifically designed calculator from our bank helps us in calculating mortgages in ways that go far beyond what we would be capable of doing in the absence of such a cultural tool.

Learning, development and schooling

Tool mediated action, including the evolution of new cultural tools, is extremely interesting from the point of view of learning and human development. Tools are “cognitive amplifiers” (Nickerson, 2005) that extend our intellect far beyond what our “natural” capacities allow. The other side of the coin is that many cultural tools are not easy to understand and use. A mathematical formula, a grammatical or science concept (Vygotsky uses the example of Archimedes’ principle) or sophisticated software are powerful when used. At the same time, they introduce obstacles and can be hard to appropriate. Sometimes the process of appropriation may extend over years, such as when learning to be a proficient scholarly writer or understanding the details and implications of a complex theory.

Vygotsky makes an interesting distinction between different forms of mediation that is important to keep in mind when discussing learning in different contexts. When children develop, they learn “spontaneous (or “everyday”) concepts” by participating in communicative practices (Vygotsky, 1986). Terms such as sister, cousin and grandfather that mediate specific kinds of relationships to significant others are picked up as elements of daily concerns; they are in a sense learned from “below.” This mediation is largely “implicit” as Wertsch (2007) puts it. In the case of “scientific (or “academic”) concepts”, such as Archimedes principle in physics or debit and credit in bookkeeping, the situation is different. It does not matter how familiar we are with bathtubs, and what happens to the water level when we enter them, Archimedes principle about the relationships between the body and the force exerted on the body by the water will not occur to us. We notice that the water level rises as we enter the tub, but the scientifically formulated relationships between our weight and the force of the water displaced is not part of our spontaneous conceptual knowledge. To understand academic concepts of this kind, we need instruction and “explicit mediation” in Wertsch’s terminology.

This distinction points to something that is important in instruction in complex societies. Some cultural tools we use as part of everyday life and their functions become clear in contexts that are transparent for the individual; we experience the consequences of using them and we learn to generalize from “below.” For instance, and to return to the example above, I have a fair understanding of what a rose looks like just by living in a certain society where roses are talked about and presented in media. In the case of scientific concepts, the situation is different in the sense that the concepts will not be part of everyday interaction. Instead, they require explicit instruction and unpacking, sometimes over long periods and through systematic pedagogy. Learning about flowers at a scientific level takes a person into botany, classifications, Latin family names, Linnaeus’ sexual system and other areas of expertise. Sometimes, and even when we have learned academic concepts, they will often not be sustained through everyday interaction, since there are few settings in which they communicate well outside specialized communities. The botanist, the accountant, the nurse and the software engineer have appropriated a range of academic concepts, but these are primarily used in their professional communities, and not over a cup of coffee or tea friends.

But, academic or scientific concepts are very important for human learning and development, and one of the important responsibilities of schooling is to familiarize children (and adults) with such cultural tools. By appropriating central scientific concepts, relevant for understanding nature (greenhouse effect, energy, virus etc.) or society (inflation, democracy and how to calculate a mortgage), people are able to access and make use of the collective experiences and insights of their society. Thus, their knowledge and understanding will be broadened and no longer limited to the personal experiences they happen to have made in daily circumstances. When someone explains what a virus is and how it spreads, we are able to appropriate knowledge that we would never have discovered by ourselves. In the words of the evolutionary psychologist Merlin Donald (2018), through systematic instruction and education we are invited to share important insights of our “cultural memory.”

The learning process involved in appropriating academic concepts, thus, is different from the one characterizing spontaneous concepts. In the former case, we are introduced to a concept, a principle or a generalization, and we have to learn by realizing what they mean. Thus, we learn in a top-down fashion by first encountering a concept, a formula or an explanation, and then we embark on a journey attempting to learn how to use these cultural tools. In this sense, learning here goes from the general to the specific or particular. Once we have learned the principles of how to calculate the volume of a cylinder, we have to apply our knowledge to different kinds of cylinders in order to become efficient users, of the cultural tool. After a while, the concept or the procedure will be appropriated, and eventually fossilized in the sense that it becomes obvious to us how it is to be used. When we see a cylinder, our conceptual knowledge will be mobilized instantaneously.

The differences between spontaneous and scientific concepts, though, should not be understood in an absolute sense. This is an analytical distinction pointing to differences in the origin of our knowledge. Some concepts that were once used by specialized groups in society, for instance the greenhouse effect or inflation, have now entered everyday discourse and are encountered frequently in media and in public discussions. Many people, outside select groups of specialists, can give a rough account of what the greenhouse effect implies or what inflation is. In teaching and learning, there are also interesting connections between spontaneous and academic concepts. We begin learning academic concepts through our familiarity with spontaneous concepts or descriptions of phenomena. We learn about the concept of force or gravity by relying on experiences we have had in everyday life of things falling to the ground or sometimes going up into the air such as in the case of helium filled balloon. Instruction, at some level, has to build on children’s spontaneous concepts for the concepts and procedures to be intelligible and possible to appropriate as scientific concepts.

Thus, within a sociocultural perspective, generalizing and particularizing are significant elements of learning, and, in many cases, we oscillate between the general and the particular as we appropriate cultural tools. For instance, many people will think that they know what the difference between a fish and a mammal is at a general level, and they will be surprised when they hear that a whale or a dolphin is not a fish even though it swims and lives in the water. Thus, what is classified as fish and mammals in science will

lead to a reconsideration by the individual when encountering a scientific conceptual framework, and a new, more specific, understanding will emerge. Within a sociocultural perspective, appropriation of cultural tools is seldom, if ever, finished. Such tools will be refined and specified as we encounter new experiences and dive into specialized intellectual territories and activities. Generalization and particularization will continue when we engage in new practices.

But, an important conclusion is that many cultural tools are unlikely to be appropriated through everyday activities. They require teachers and explicit instruction. Writing, scientific discourses in many disciplines, mathematical practices, use of tabular representations, a foreign language and the principles of bookkeeping exemplify cultural tools where there are obvious thresholds, and where systematic pedagogy is a vital premise for appropriation.

Learning in the zone of proximal development (ZPD)

One of the most well-known and most discussed ideas in the Vygotskian framework for analyzing learning and development is the concept of ZPD. Vygotsky (1978, p. 90) argues that “learning creates a zone of proximal development; that is learning awakens a variety of internal developmental processes that are able to operate only when the child is interacting with people in their environment and in cooperation with his peers.” Thus, as the child appropriates concepts (round, square) and skills (knowing how to add one-digit numbers), there are neighboring forms of knowing that metaphorically speaking come within reach, but where the child temporarily will need the assistance of more “capable peers” to manage a task. ZPD is defined as

the distance between actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers (1978, p. 86).

The concept of distance here implies that there are some insights and skills that the child (or the adult) already possesses (adding one-digit numbers), but where he or she is dependent on interactional support from more “capable peers” when encountering a more complex, but similar, task. In this example, we may think of the skill of adding a one-digit number with a number that has two digits (3 plus 12). If the child is unable to handle this, the adult support can take a variety of forms, for instance asking questions that are relevant and/or simplifying the problem (if you add 2 and 3, what do you get? What do you have to add then?). In the case of a physical skill, such as tying one’s shoelaces, the parent will simplify the appropriation by showing how to place the shoelaces when starting, how to cross them and so on (Nilholm and Säljö, 1996). Thus, for knowledge and skills that are within the ZPD, the child needs temporarily to “borrow” the skills of a more knowledgeable partner in the activity. After some practice, the child will have appropriated all the elements of the action and will be able to perform the task without support, or, as Vygotsky puts it, “independently.” Later on, the child will be able to handle such tasks while, at the same time, engaging in other activities such as talking to a friend or watching television. The skills needed have been appropriated to a level where they require almost no conscious attention.

All learning thus creates ZPDs. When we learn something, new ZPDs appear, and new knowledge comes within reach. In Vygotsky’s terminology, new “buds” of mental processes appear, that is, knowledge and skills that are still at an early, embryonic state, and which need to mature for the individual to be able to use them independently. From this perspective, there is a view of learning and development, where humans are seen as constantly engaged in appropriating new knowledge as they encounter new challenges. We do not reach final stages where our intellectual development is complete (as developmental theories often claim), rather we learn when we encounter new practices or cultural tools that may deepen or extend our knowledge. These ideas of new ZPDs appearing when we learn are not specific to children; they characterize learning throughout life.

Another reason why Vygotsky emphasized the role of ZPDs is that he argued that it is in the zone of proximal development that the child is sensitive to instruction. Thus, the child’s intellectual capacity in a particular setting has reached a level where he or she can understand and follow the explanations and support provided by the partner, thus making it possible to appropriate a skill or a concept. This means that knowing how to intervene in ZPDs is an essential constituent of the professional skills of teachers and other instructors. In the sociocultural literature, this kind of support is referred to as “scaffolding”, following a famous article published by Wood et al. (1976). There is a whole literature on the role of scaffolding in teaching and learning in many areas: mathematics, science, language learning etc.

Conclusion: the role of learning in the sociocultural perspective

Learning is a central concept within the sociocultural perspective. It is by appropriating cultural tools that people develop and are able to utilize significant elements of the knowledge and skills of the cultural memory of their society. This assumption differs from most theories of human development, which generally construe development as a process of maturation. The latter perspective, characteristic of the developmental psychology of Jean Piaget, describes development as essentially parallel to biological development. As the child grows older, his/her cognitive, communicative and physical capacities evolve through different stages until they reach those of adults. The sociocultural perspective represents an alternative view, where learning and appropriation are seen as preceding development. It is by appropriating cultural tools (language, sign systems and other cultural tools) that we develop

into competent participants in cultural practices. Simply put, learning comes first, development follows. And there is no final cognitive stage or level of knowledge; we continue to appropriate new knowledge and skills throughout our lives. In a sense, we are doomed to learn, and this is especially true if we live in societies where cultural tools change at a rapid pace.

The sociocultural perspective and the concepts of cultural tools and appropriation imply that learning and development are viewed in the context of the socialization practices of societies that are situated in time and history. Jerome Bruner (1997), in a famous article with the title “Celebrating diversity”, published on the occasion of the centennial of the birth of Vygotsky and Piaget, explicated the tensions between the two perspectives on learning and development. For Piaget, who is a universalist, development is a process of maturation and unfolding of intellectual capacities that reside within the individual mind. In such a tradition, the cognitive stages that characterize development are central, and learning plays a minor role. For Vygotsky, who is a contextualist and has an interest in understanding the relationships between cultural practices and human development, learning is the process by means of which individuals come to share the insights and skills of the society in which they are grow up. Thus, in the latter perspective, culture and cultural practices, including the cognitive and material artifacts, are formative of mind.

It is important to note that the sociocultural perspective does not imply that the human mind is influenced by culture, as is sometimes argued. Rather, the claim is much stronger and precise: culture is constitutive of mind. It is by appropriating cultural tools that we develop mental and practical skills relevant for social activities. In this sense, culture and cultural practices “hi-jack” the human mind as Donald (2001) puts it, and what we learn and know are the insights and skills of the cultural memory of our society. For Vygotsky, this process of cultural learning in its most powerful forms begins when the child is able to use language as a means of communication. When entering this phase at about one to two years, the child is able to live *in* the world and simultaneously increase his or her capacity to communicate *about* the world and his or her own activities. Vygotsky argued that it is almost as if we are born twice: once as biological beings (at birth), and then again when we are able to use language and appropriate the cultural tools of our society.

It is almost a hundred years ago that Vygotsky formulated his ideas. During a short and difficult life, he managed to articulate a perspective on learning, development and communication that continues to inspire scholars in a range of disciplines as well as practitioners in education and teacher education. His writings are fascinating, but sometimes they are sketches with original ideas and observations rather than finalized texts. There are several elements of his conceptual framework that he did not have time to develop in depth. This is one of the sources of disagreements among scholars as to what he meant. It is also obvious that the contexts in which we, as contemporary readers, understand his writings are very different from those that characterized his time. Relationships between adults and children have changed, the material circumstances are different as is the media situation and the ideals of education and teaching and learning. The Vygotskian account of learning and the sociocultural formation of mind has a lot to offer, and the theoretical and practical implications of this perspective in the context of technologically and socially complex societies inspire further research across the world.

A brief history of the learning sciences

Interest in human learning and effective ways of supporting learning through teaching and other forms of instruction can be traced back for millennia. The *learning sciences* as an emerging academic field originated in the 1980s (Hoadley, 2018). The emergence of the learning sciences was based on three groundbreaking shifts.

First, the idea of context and learning in situ moved to center stage. The shift toward context made it possible to consider the role of the social and physical world in and through which people learn as a basis for theorizing and understanding learning. Studying learning in context was a response to the cognitive paradigm of research on learning and instruction. As (socio-)constructivist and socio-cultural learning theories (e.g., Vygotsky and Cole, 1978) were increasingly adopted, the research focus shifted from studying the individual's cognition (cognitivism) in isolation to studying the learning of individuals and groups in their physical and social environments (e.g., Brown et al., 1989; Scardamalia and Bereiter, 1991). This development is mirrored in the influential 1993 special issue of the journal *Cognitive Science* which contained "a debate among proponents of two distinct approaches to the study of human cognition" (Norman, 1993, p. 1) and led to an increased interest in *situated action* or *situated cognition*, "emphasizing the role of the environment, the context, the social and cultural setting, and the situations in which actors [learners] find themselves" (p. 1). Viewing learning as driven by both internal and external factors led to a theoretical multiplicity, a tradition that the learning sciences continue to advance by staying open to new theoretical perspectives with utility for better understanding and supporting human learning.

Second, the understanding of learning as situated and influenced by socio-cultural and physical contexts required a new set of methodological approaches that allowed to capture (ongoing) learning as understood from these new perspectives. Established prior paradigms from (educational) psychology such as aptitude-treatment interaction (Cronbach and Snow, 1977) were questioned, as these did not adequately mirror the way learning happens within complex school and out-of-school settings, missing important aspects of ongoing learning. As a consequence, research in school and out-of-school learning environments became a dominant paradigm, necessitating the development and use of qualitative, quantitative, and mixed-methods approaches for capturing and facilitating learning (e.g., design-based research). Notably, the learning sciences are characterized by a methodological multiplicity that continues to develop in light of recent technological developments (e.g., Rosé, 2018; Shapiro and Garner, 2021; Sommerhoff et al., 2018).

Third, the learning sciences are also associated with a shift toward interdisciplinary research fueled by the rise of computer science, research on artificial intelligence, computer learning (i.e., how do computers learn?), and computerized learning (i.e., how do humans learn using computers or other technologies?) (e.g., Bobrow and Collins, 1975; Sleeman and Brown, 1982; Wenger, 1987). Trailblazing scholars, including Roger Schank and Seymour Papert, anticipated that computers would radically transform human learning and research on learning, also considering computers as tools that could advance mental structures through the production of personal (learning) designs (e.g., Papert, 1980). In particular, the extension of the phenomenon of *learning* from humans to computers and the comparison and combination of both agents (i.e., people and computers) brought together researchers from a diverse range of fields, including education, psychology, and computer science. For example, major interdisciplinary research lines were the implementation of learning in programming languages (e.g., LISP, LOGO), research on artificial intelligence and learning (e.g., Anderson et al., 1985), and the development of computer-supported learning environments

(e.g., [Cognition and Technology Group at Vanderbilt, 1992](#)). Corresponding interdisciplinary endeavors were, for example, nourished by first specific funding programs for the learning sciences, such as the “Cognitive Consequences of Programming” of the US National Institute of Education ([Pea and Linn, 2020](#)). The learning sciences have since participated in shaping a vision of computational innovations as mediating new and more advanced forms of learning (including computer-supported collaborative learning, see also [Lee, 2017](#)).

Together, these conceptual, methodological, and (inter-)disciplinary developments led to the formation of a community of researchers, which transcended the hitherto disciplinary boundaries and created the necessity for novel opportunities for meeting (e.g., conferences), publishing (e.g., journals), and funding (e.g., special programs). In 1989, the AERA special interest group “Education in Science and Technology” was founded and later also the sister special interest groups “Learning Sciences” and “Advanced Technologies for Learning” which became a central outlet for the developing learning sciences community. As a consequence of the significant growth of the learning sciences community in terms of impact and spread during the 1980s and 90s, higher education opportunities and separate scientific publication outlets for these areas of research became cogent for the further development of the field ([Kolodner, 2004](#)). The *Journal of the Learning Sciences* (JLS) was established in 1991 and the first doctoral program including the terms “Learning Sciences” in its title was launched at Northwestern University in 1992. The doctoral program evolved from the Institute for the Learning Sciences, which was founded at Northwestern in 1989. Parallel, the first International Conferences of the Learning Sciences (ICLS) and of Computer-Supported Collaborative Learning (CSCL) were held in the early 1990s ([Kolodner, 2004](#); [Sawyer, 2014](#)). Since 1995, both conferences have repeated regularly in a biannual format. To bring these conferences and the Journal of the Learning Sciences (JLS) under one institutionalized umbrella, the *International Society of the Learning Sciences* (ISLS) was founded as a non-profit professional society in 2002. In particular, ISLS brought together partially different communities clustering around the learning sciences and CSCL ([Hoadley, 2018](#)). To address the partially different interests of the CSCL community, the *International Journal of Computer Supported Collaborative Learning* (ijCSCL) was established in 2006 ([Stahl and Hesse, 2006](#)).

Research and community building in the context of the learning sciences and CSCL also emerged internationally beyond the North American focal point ([Pea and Linn, 2020](#)). For example, the European Research Network *Kaleidoscope* was established in 2004 based on a funding program by the European Commission that centered on Technologies for the Information Society. The network focused on *technology enhanced learning* and brought together over 1000 researchers from about 100 research units and approximately 20 countries, spanning the fields of computer and social sciences and education, with the goal to integrate different research communities in the context of technology-enhanced learning and to inform knowledge transfer between education, industry, and the wider society ([Laurillard et al., 2007](#)). Within Kaleidoscope, special interest groups on CSCL and on Inquiry Learning became focal points for new scholarly communities with strong conceptual and methodological relationships to the learning sciences. Many of these European CSCL researchers later joined the CSCL community within ISLS. Also in 2004, the *Asia-Pacific Society for Computers in Education* (APSCE), which aims to promote the conduct and communication of scientific research related to all aspects of the use of computers in education, was formed, evolving from the Asia-Pacific Chapter (APC) of the *Association for the Advancement of Computers in Education* (AACE), which itself was established in 1994.

Based on these national and international developments and its theoretical, methodological, and disciplinary pluralism, the learning sciences as an academic field has developed into a multidisciplinary “tent” ([Nathan et al., 2016](#)) that represents an international community and an emerging discipline (see also [Evans et al., 2016](#)). This is also reflected within the *Cambridge Handbook of the Learning Sciences* ([Sawyer, 2005, 2014](#)) and the *International Handbook of the Learning Sciences* ([Fischer et al., 2018b](#)), the contents of which comprise conceptual, methodological, and epistemological foundations of the learning sciences as well as an overview of current research. The handbooks serve as introductions to learning sciences as a community and field of research for students and researchers. The handbooks also capture the historical development of the learning sciences including proposals for future research trajectories for the academic field.

The (self-)concept of the learning sciences

Since its formation, the ISLS considers itself as a *community of practice* ([Wenger, 1999](#)) bringing together academics, professionals, and students who are seeking to advance the sciences and practices of learning. It investigates “fundamental inquiries on how people learn alone and in collaborative ways, as well as on how learning may be effectively facilitated by different social and organizational settings and new learning environment designs, particularly those incorporating information and communication technologies (ICT), as in computer-supported collaborative learning (CSCL)” ([ISLS, 2009](#), p. 1). It is a community that addresses authentic learning in contexts in which learning would naturally happen ([Kolodner, 2004](#)). The ISLS also has an educational mission, for example, to foster high quality learning sciences programs in higher education internationally. This educational aim led to the foundation of the *Network for Academic Programs in the Learning Sciences* (NAPLeS) at an ICLS conference in Sydney in 2012. NAPLeS’ first activities were the establishment of a world-wide directory of affiliated learning sciences master’s and PhD programs, a collection of syllabi for higher education introductory courses to the learning sciences, and a webinar series with a selection of learning scientists including pioneers who advanced groundbreaking insights that fundamentally shaped the learning sciences, including Carl Bereiter, Allan Collins, Jim Greeno, and Marlene Scardamalia. To date, NAPLeS has developed into an essential component of ISLS’s educational activities.

The unification of the biannual ICLS and CSCL conferences into the “ISLS Annual Meetings,” the first of them held in Bochum, Germany in 2021, reflects the co-development of both learning sciences and CSCL and the growing coalescence of the learning sciences as an emerging discipline. However, even with this convergent development, the learning sciences remain a community that distinguishes itself through theoretical, methodological, and disciplinary pluralism. Within this pluralistic understanding of studying learning as it unfolds within a social and physical context, certain core concepts and methods exist within the learning sciences that are orbited by other adjacent concepts and methods (e.g., [ISLS, 2009](#); [Nathan et al., 2016](#); [Sommerhoff et al., 2018](#)). This makes the learning sciences a dynamic society that aims to understand and foster human learning in authentic settings ranging from early childhood to adult education and informal learning over the life span.

Theories of learning and guidance in the learning sciences

Theorizing learning

From the perspective(s) of the learning sciences, learning is predominantly considered from cognitive and socio-cultural perspectives on learning, with embodied and neuroscientific learning theories expanding. However, what can be attended to as learning and what it means to learn in different contexts can be described differently depending on the theoretical perspective. Thus, a multitude of nuanced learning theories have evolved over time, which expand the broad theoretical approaches for more specific learning situations, in particular also combining learning theories with educational perspectives on how to support learning in these situations.

The cognitive revolution (see [Miller, 2003](#)), starting in the 1950s, led to a shift away from behavioral learning theories and was able to better account for many aspects of individual learning. However, subsequent research also highlighted multiple phenomena related to learning, for example individuals showing different performance in different contexts (e.g., [Carragher et al., 1985](#)), which could not be accounted for adequately by these theories. Corresponding findings led to socio-cultural learning theories, which extended current cognitivist conceptions of learning. The research of the Soviet psychologist Lev Vygotsky had a major influence (also outside of Russia), based on the re-publication (and partial revision) of his work “Mind in Society” in the late 1970s ([Vygotsky and Cole, 1978](#)). This conception of learning takes the perspective that all learning is socially embedded, leading to the focus on learning (within) communities and, for example, knowledge building ([Scardamalia and Bereiter, 1991](#); see section on Computer-Supported Collaborative Learning below) within these communities. This conception was further developed within the learning sciences context with concepts such as (i) “situated learning/cognition” ([Lave and Wenger, 1991](#)), positing that all knowledge is intrinsically linked to a specific social, cultural, and physical context, (ii) “distributed cognition” ([Hutchins, 1995](#)), focusing on how cognition is distributed over an environment rather than taking place solely in the individuals’ minds, and, (iii) “collective knowledge construction” ([Cress and Kimmerle, 2018](#)), which focuses on the joint creation of knowledge and content from relatively small groups to large communities, for example in wikis with hundreds of contributors.

For example, situated cognition draws on ideas from socio-cultural theories of learning and theorizes that learning is principally a social process ([Brown et al., 1989](#)) that emerges in interaction with others ([Vygotsky and Cole, 1978](#)). Within this theoretical approach, the notion of cognitive apprenticeship takes precedence, which refers to the enculturation of learners into the authentic, established, and valued practices of a community with the aim of becoming full members of that community ([Lave and Wenger, 1991](#)). Learning environments that are designed based on socio-cultural learning approaches support learners to interact with others toward engaging in ways of doing that are established and valued within the surrounding social context (e.g., [Engle and Conant, 2002](#)). This may mean identifying specific disciplinary practices and recognizing how learners use resources and approach content related to the discipline in ways that are recognizable and representative ([Engle and Conant, 2002](#)).

The shift from learning as something within an individual’s mind toward considering learning as situated within a community of practice means inviting learning to be theorized, captured, and designed for at multiple levels within the larger socio-cultural and historical system of relevant practices. This alludes to another central theoretical background of learning from a learning sciences perspective: Activity theory. While its origins go back to the Soviet psychologists Sergei Rubinstein and Alexei Leont’ev, it was taken up by several Western scholars (e.g., [Engeström, 2000](#)) and further developed, for example, through [Danish’s \(2014\)](#) work that employed an activity theoretical lens for educational design and analysis to analyze complex socio-cultural systems and their interactions. While activity theory aims at describing a single individual, it positions this individual in a broader context, a socio-technical system, that includes the community as a whole and, as crucial aspects of this community, their specific cultural tools, their rules, and the division of labor, all of which are necessary to describe the single individual within this context. Activity theorists often use the so-called activity triangle that can be applied as an analytical frame toward understanding an individual, a group, a community, or a system in context, their interactions, and possibly their changes over time. Besides this general necessity for context, activity theory also introduces a hierarchical structure of activity, which can be transferred to the notion of the multi-leveled nature of learning. [Roschelle \(1998\)](#) roughly characterizes these levels as “cultural, conscious, and automatic” (p. 243). While these three levels are often not considered explicitly enough, they inform why learning sciences research includes research approaches that range from the cultural level (e.g., using an ethnographic perspective) and the automatic level (e.g., using neuro-cognitive approaches). While less prominent in the learning sciences as a theoretical underpinning, a similar argument can be based on Newell’s unified theories of cognition ([1994](#)), which positions learning on different time scales from milliseconds (biological processes) to seconds (cognitive and rational processes) to hours, days, weeks, and beyond (socio-cultural, organizational) (see also [Nathan and Alibali, 2010](#)).

Each of these concepts for learning highlights that learning is situated (e.g., [Greeno, 2011](#)) in the sense that it is situated within a community of individuals, situated in certain situations, and situated within certain objects or artifacts, which might be used as means for learning. This view of learning can be characterized as core to the learning sciences; however, there is also a broad periphery of less radically social conceptions of learning around this core, which are used within the learning sciences and lead to tensions and synergies ([Danish and Gresalfi, 2018](#)).

An example of a specific theoretical approach trying to combine cognitive and socio-cultural perspectives is learning with multiple representations ([Ainsworth, 1999, 2018](#)). This approach gives a specific account on how multiple representations, such as texts, videos, or augmented/virtual reality impact learning and how they can (individually and in combination) be designed to support optimal learning. However, learning through multiple representations goes beyond purely cognitive theories of learning (e.g., [Mayer, 2014; Sweller et al., 1998](#)) by building on semiotic and sociological perspectives to better address the role of the context in the analysis and the design of representations for learning.

The learning sciences is also increasingly focusing on embodied ([Alibali and Nathan, 2012; Ma, 2016; Shapiro, 2019](#)) and neuro-cognitive learning theories ([Sousa, 2010; Varma et al., 2018](#)). The former point to the importance of the human body for cognition and learning, in particular regarding the sensory, perceptual, and the motor/kinesthetic systems as well as how bodies and a combination of bodies are positioned together to facilitate relationships to domain-specific ideas and concepts. It is rooted in part in theories from developmental psychology emphasizing that knowledge and thought are not only reflected in specific actions, but that actions, for example specific motions and gestures, can also support learning (e.g., [Goldin-Meadow, 2005](#)). Finger-counting or drawing geometric objects in midair to illustrate one's cognition when solving mathematical problems are two examples of embodied cognitive approaches to learning (e.g., [Alibali and Nathan, 2012](#)). Corresponding theories underline that effective learning environments consider possibilities for learners to engage in (bodily) actions, for example by using specific analog or digital manipulatives that can support these actions (e.g., [Abrahamson, 2009](#)).

While theories of embodied cognition and their implications are already permeating learning sciences research, neuro-cognitive learning theories are only starting to change current conceptions of learning as examined in the learning sciences (e.g., [Sousa, 2010](#)). Cognitive neuroscience has already made impressive progress on explaining cognition of individual learners focusing on short time-scales (partially at the level of fractions of seconds) in relatively controlled, laboratory settings (e.g., [Eden et al., 2004; Postle, 2020](#)). However, this is currently at odds with the learning sciences focus on learning in situ ([Varma et al., 2008](#)), which centralizes authentic, contextualized, social processes often related to timescales of days, weeks, and months.

Supporting learning

The design of learning environments in a broad range of educational contexts

Responding to the multilevel and multi-perspective view of learning, research that aims to support learning typically involves challenging situations that ask learners to grapple with tasks and problems “for which they do not have rote solutions or for which they cannot simply call upon a memorized factoid” ([Fischer et al., 2018a](#), p. 4). These challenging situations are typically embedded in information-rich environments that include interaction with other humans and technology.

Learning sciences research is addressing both the design of formal and informal learning environments. For example, formal learning environments have been investigated more systematically for primary and secondary mathematics and science education (e.g., [Belland et al., 2017](#)) and for argumentation and collaboration in different fields of higher education ([Jeong et al., 2019](#)). Informal learning environments have, for example, been studied in museums ([Lyons, 2018](#)) and in maker-centered learning spaces that can be situated within a range of educational institutions and that provide opportunities for people to engage with high- and low-technological tools and materials and can foster technological innovativeness ([Peppler et al., 2016](#)). Studying learning within out-of-school settings (rather than school settings) allows the advancement of knowledge about highly innovative designs for learning, as well as building inroads for later possible adaptation in school settings. Work on out-of-school settings also includes considering outdoor and indigenous knowledge spaces for broadening cultural relationships within STEM learning (e.g., [Litts et al., 2021; Tzou et al., 2019](#)).

In addition, learning sciences research considers the facilitation of learning and expertise across the lifespan. Although a majority of studies address K-12 learners, there is increasing interest in learning within early childhood (e.g., [van Horne and Bell, 2017](#)) and family settings (e.g., [Roque, 2016](#)). Research on expertise development has investigated environmental conditions and support for learners in a much broader age range, including learning at work and through professional development ([Ludvigsen and Nerland, 2018; Reimann and Markauskaite, 2018](#)).

Pedagogies

Learning scientists have systematically employed and explored pedagogies that acknowledge the multilevel nature of learning and address the design and use of challenging learning tasks (e.g., [Eberle, 2018](#)). They share the basic assumption that complex skills cannot be learned well solely through reading books, being exposed to teacher presentations, or solving massively simplified “toy” problems. Instead, situations are seen as more supportive of learning if they resemble real problem-solving situations in important dimensions of agency ([Brown et al., 1989](#)). Among these important dimensions are (a) agency in applying and transferring knowledge to new situations, cases, and problems; (b) agency in generating new knowledge (e.g., on natural and social phenomena), that is, to what extent learners take responsibility to find out about important mechanisms, effects, rules, or relations to explain natural

or social phenomena; and (c) agency in coordinating with, explaining to, and negotiating with others the processes and outcomes of knowledge generation and knowledge application (argumentation and knowledge building).

In the following, we briefly introduce three types of pedagogies, (1) learning through problem-solving, (2) learning through inquiry, and (3) learning through design. In addition, we sketch the concept of (4) scaffolding as it probably is the most prominent form of instructional support in complex learning environments that result when the three pedagogies are applied.

- (1) Learning through problem-solving: Environments for learning through problem-solving involve learners' engagement with complex problems with the goal of learning (Hmelo-Silver et al., 2018). Problem-solving pedagogies typically focus more on learners' agency with respect to applying and transferring of canonical knowledge (agency dimension a) than on learners' initial discovery of that or new knowledge. Highly productive lines of research have addressed an individual's learning through solving problems. One central research area has addressed the issue of cognitive load that arises through complex problems for learners with little prior knowledge, for example while trying to solve mathematical problems. Goal-free instruction and worked-out examples have been suggested as scaffolding associated with a reduced amount of cognitive load in comparison to solving the problem by oneself (Sweller et al., 1998). Four Component Instructional Design (4C/ID) is an instructional approach that builds on cognitive load theory and that has been applied in many contexts, including higher education (e.g., Sommerhoff et al., 2021) and vocational education (e.g., van Merriënboer and Kirschner, 2018).

Another longstanding and influential line of research that is associated with learning through problem-solving has been the investigation of intelligent tutoring systems (ITS or cognitive tutors, Graesser et al., 2018b). With ITS, learners try to solve problems presented to them on a computer, while ITSs use artificial intelligence to assess the process and the outcomes of a learner's attempts to solve a problem, to build a model of a learner's skills, and to offer feedback and scaffolding, for example, through more difficult or easier tasks, strategic hints, prompts, or examples. Beyond supporting individual learning through ITS, learning scientists began to explore the effects of collaborative learning within small group problem-solving that employ an ITS (Kumar and Kim, 2014; Rummel et al., 2016). Also, some approaches to game-based learning and simulations build on learning through problem-solving (Chernikova et al., 2020; Clark et al., 2016; Fields and Kafai, 2018).

There has been a long tradition of employing collaboration to enhance the effects of learning through problem-solving. The most prominent example is problem-based learning (PBL). In PBL scenarios, small groups of 5–12 learners collaborate around complex, domain-specific case problems (Dochy et al., 2003; Hmelo-Silver and Barrows, 2015). A main focus with respect to collaboration in this context is on pooling of resources: The group, supported by a tutor, identifies the knowledge needed to solve the case, for example to come up with an accurate diagnosis or a promising intervention for a patient case problem in medical education. The members of the group search for resources that offer access to the missing knowledge and share their findings in the group. In addition, further questions, including what makes tutors effective in PBL, have been addressed in research (Schmidt et al., 2011).

Recently, work within the learning sciences has started investigating the knowledge and skills necessary to engage in complex collaborative problem-solving (Graesser et al., 2018a) and has designed learning environments to facilitate them. For example, there have been approaches to use agent-based simulations where one or more human learners have interacted with collaboration partners that were simulated by a computer (e.g., Graesser and McNamara, 2010).

- (2) Learning through inquiry: Inquiry learning requires learners increasingly to take responsibility to find out about important mechanisms, effects, rules, and relations to explain natural or social phenomena. In inquiry-based learning environments, learners are supposed to explore phenomena, use disciplinary and generic tools and methods (e.g., measurement devices, lab protocols, spreadsheets), and come up with sound descriptions and explanations of the observed phenomena (see Pedaste et al., 2015). Many computer-supported inquiry learning environments have been developed for and employed in middle school science classrooms (e.g., Linn et al., 2003). Yet, increasingly, other domains (e.g., historical inquiry; Voet and de Wever, 2016) and other educational contexts (i.e., higher education; De Jong et al., 2013) have been explored in relation to inquiry-based pedagogies as well.

Building on research relating to the many problems that learners experience when engaging in knowledge generation through inquiry (e.g., De Jong and van Joolingen, 1998), several approaches to guided inquiry and discovery (in contrast to free discovery) have been developed and investigated (Donnelly et al., 2014). Typically, inquiry environments that learning scientists have developed include opportunities to interact with peers in small groups or whole classrooms in inquiry activities, such as formulating or evaluating hypotheses, generating evidence, or drawing conclusions and revising an explanation (Slotta et al., 2018).

- (3) Learning through designing: Pedagogies that build on learning through designing involve tasks in which learners engage in the process of utilizing disciplinary knowledge for generating ideas, devising a problem space, building prototypes, and evaluating and iteratively refining a product aimed at solving a challenging situation, often a provided problem. These pedagogies consider agency of the learners for engaging in inquiry activities by which they derive the disciplinary knowledge as well as the knowledge on the constraints and affordances of the problem, both of which are needed for designing, refining, and evaluating the product. Building on foundational work in the early 2000s (see Kafai, 2012; Kolodner et al., 2003), the field has substantially advanced by introducing more recent approaches to learning through designing digital games (Fields and Kafai, 2018), including augmented reality (Enyedy and Yoon, 2021), research on the maker movement (Halverson and Peppler, 2018), research on design thinking in different educational contexts (Svihla and Reeve, 2016; Goldman and Kabayadondo, 2016), and considering alternative tools and materials for the study of equitable STEM education through design activities (e.g.,

Peppler and Glosson, 2013). Design pedagogies typically include a focus on interaction among peers where collaboration has quite different functions, including peer feedback on initial ideas, inter-group competitions with respect to the performance of the designed product, and collaborative knowledge building through joint experimentation and discussion (Kolodner et al., 2003; see Fields and Kafai, 2018). Design pedagogies typically initiate and support peer communities using either digital contexts such as internet platforms (e.g., Scratch; see Fields and Kafai, 2018) or material contexts, for example in the context of science learning (e.g., Clegg and Kolodner, 2014).

Theoretical foundations of learning through designing pedagogies are often constructionist, that is assuming that learning happens best when learners come to know the world while creating personally meaningful projects that can be publicly shared (Papert, 1980). A focus lies on the creation and manipulation of tools and materials. For example, in the process of design, materials that are being manipulated turn into “objects-to-think-with” (Papert, 1980, p. 11) that make it possible for learners to become epistemologists who observe their own learning as well as personal and multiple ways of knowing (Papert and Harel, 1991). Studying particular material design situations thus allows research to expand on these theoretical ideas within constructionist approaches toward a richer understanding of ongoing learning within digital and physical learning through design situations.

- (4) Scaffolding: Referring to the concept of the Zone of Proximal Development, the zone between what learners can do on their own compared to what they can do with the support of more experienced others (Reiser and Tabak, 2014; Vygotsky and Cole, 1978), pedagogies preferred by learning scientists are centered around complex situations that are typically somewhat too challenging for learners themselves. Initially, the learners cannot master these problem-solving, design, or inquiry tasks without additional support. Of the various forms of potential additional instructional support that exist (e.g., feedback, additional information, additional incentives), the learning sciences community has put particular focus on the idea of scaffolding (Wood et al., 1976). Scaffolding refers to instructional support that enables learners to master tasks that are outside their reach without this support. Scaffolding is typically offered by more knowledgeable others or by (intelligent) computer systems. Wood et al. (1976) identified main functions of scaffolding which include sparking situational interest (*recruitment*, p. 98), reducing the complexity and difficulty of tasks (*reduction in degrees of freedom*, p. 98), keeping learners focused on their goal (*direction maintenance*, p. 98), (4) highlighting crucial features of a task (*marking critical features*, p. 98), (5) motivating disappointed learners (*frustration control*, p. 98), and (6) providing solutions and models of a task (*demonstration*, p. 98). Building on Bruner’s original work, several taxonomies of scaffolding functions emerged that differ mostly with respect to whether they address what is to be learned (e.g., scaffolding for joint sense-making or for building a hypothesis, e.g., Quintana et al., 2018) or whether they refer to how the learner is supported (e.g., prompting, hinting, channeling, Pea, 2004).

A joint assumption of scaffolding approaches is that the effectiveness of this kind of support depends on its contingency and time-liness. Scaffolding is considered to be temporary and needs to be removed (or faded) when the learner does not need it anymore because scaffolding can also be detrimental for learning (expertise reversal effect; Kalyuga, 2007). Thus, scaffolding requires a dynamic assessment of knowledge and skills, and consequential adaptive interventions—a complex interplay of guidance and self-regulation with respect to each and every individual learner (see Plass and Pawar, 2020). As this seems hardly possible in typical classrooms with only one or two teachers or tutors and 20 or more learners, technology and peers as sources of scaffolding increasingly became the focus of research (Tabak, 2004). Although theoretically straightforward, a recent meta-analysis found mixed evidence on the effects of instructionally adapting the scaffolding to the inferred needs of the learners (Belland et al., 2017).

There are several lines of research on scaffolding for individual learning (Belland et al., 2017). Scaffolding by using examples, so called example-based learning, is certainly one of the more systematically researched approaches to scaffolding (Renkl and Atkinson, 2003). In this approach, learners have the opportunity to follow someone else’s steps in solving a difficult problem, typically without further explanation of why these steps were taken. Then, the learners typically have to self-explain the steps by using domain knowledge (e.g., principles of probability calculus). This type of scaffolding example has been used effectively in several domains. In particular, studying and self-explaining examples was more effective than engaging in problem-solving activities for learners with little prior knowledge (see van Gog and Rummel, 2018).

Computer-Supported Collaborative Learning (CSCL) and its approaches to facilitating learning

CSCL is concerned with groups that coordinate, co-regulate, and engage in argumentation and knowledge building in problem-solving, inquiry, and design tasks in technology-rich environments. In CSCL research, technology conceptualizations include providing complex and dynamic contexts for these activities and associated pedagogies, as well as enabling and structuring peer collaboration of small and large groups. The *International Handbook of Computer-Supported Collaborative Learning* (Cress et al., 2021a,b) identified common ground of CSCL with other areas of the learning sciences but also differences with respect to phenomena, theories, and methods.

Collective knowledge construction within the learning sciences transcends a purely cognitivist perspective by building on key aspects of socio-cultural perspectives (e.g., Engeström, 2000; Vygotsky and Cole, 1978). Here, the group level as well as (group/cultural) artifacts, alongside individual learning are taken into consideration, with the aim to identify how to support both group and individual learning in the best way possible. Issues around *knowledge building* (see Scardamalia and Bereiter, 2021) have characterized CSCL research for many years. Conceptual and empirical research yielded design principles for learning environments in which learners in school create and share new knowledge for themselves, their class, or even the whole school through collaborative reasoning. The technology enabled the creation and linking of arguments, peer feedback on the arguments, and the revision of the

arguments. The approach has been taken up in many places around the world and further investigated through implementations in schools (see [Chan and van Aalst, 2018](#)) and detailed network analyses ([Oshima et al., 2012](#)). Some more recent theories of collective knowledge building ([Cress and Kimmerle, 2018](#); [Stahl, 2005](#)) describe and explain how groups of people, from small groups working on one project, to organizations developing several new projects, to large communities producing online artifacts, co-create new knowledge, both regarding their individual knowledge but, in particular, knowledge at the group or community level. The focus of collective knowledge construction theories lies in recognizing a multi-level and multi-agent structure that consists of individual learning and acting, as well as group learning, interaction processes, and artifacts (e.g., [Cress and Kimmerle, 2008](#)).

Often, learners' engagement in collaborative knowledge building and argumentation have been analyzed from different theoretical perspectives, reflecting the different disciplinary roots and multiple epistemological backgrounds of the learning sciences. These perspectives include socio-cognitive approaches which are mainly interested in individual learning and focus on discussion and argumentation as potentially facilitating contexts of learning (e.g., [Stegmann et al., 2012](#)); dialogic education which considers dialogic argumentation as a major cultural tool to shape individual thinking (e.g., [Philipson and Wegerif, 2016](#)), as well as approaches to collaborative argumentation mainly interested in understanding and advancing the human capacity to jointly generate knowledge and resolve conflicts (e.g., [Baker et al., 2021](#)).

An important discovery of research on collaborative learning has been that collaborative argumentation and problem solving among learners is not productive in a broad range of contexts because learners often fail to work together (e.g., [Barron, 2003](#); [Weinberger et al., 2010](#)). Two lines of research examine forms of support that make productive collaboration more likely.

- (1) *Awareness* research examines different forms of awareness support for self- and co-regulation in groups. For example, learners are provided with information about the prior knowledge of each collaboration partner or about the amount/quality of their own contributions compared to other learners in the group (cf. [Bodemer, 2018](#)). The effects of awareness support are mixed. It is likely that the extent to which this additional information can actually be used to improve collaborative problem-solving, inquiry, and design depends heavily on the self-regulation skills and learning preferences of the individuals and the group ([Jeong et al., 2019](#)). A promising new line of research uses dashboards to inform and support the teachers in their monitoring and scaffolding of computer-supported collaborative learners ([Tissenbaum and Slotta, 2019](#); [Van Leeuwen, 2015](#)).
- (2) *Scripting and orchestration* for groups: Research on CSCL has successfully broadened the concept of scaffolding individuals in groups and scaffolding groups as a whole (see [Kim et al., 2020](#)). Research on the design and the effects of collaboration scripts has emerged from an uptake and the extension of two complementary notions of the term script as a cognitive structure that enables understanding and acting ([Schank, 1999](#)) and as an instructional method to improve collaborative learning ([O'Donnell et al., 1987](#)). Through collaboration scripts, complex collaborative tasks are segmented into "scenes" and learners are supported by role specifications and, in some cases, engagement in individual subtasks such as formulating questions or arguments (see [Fischer et al., 2013](#)). Technology can be used for segmentation and coordination (e.g., [Manathunga and Hernández-Leo, 2018](#)) as well as to highlight a role, to provide just-in-time prompts and guidance, and to adapt the level of support (e.g., [Amarasinghe et al., 2019](#)). Collaboration scripts were found to be particularly effective for learning collaboration skills (e.g., engaging in dialogic argumentation in a discussion) and, to a somewhat lesser extent, for domain learning, and segmentation into scenes proved to be the most effective approach to scaffolding (see [Vogel et al., 2017](#)). A negative effect of structuring collaboration on motivation has not received support from the existing evidence (see [Radkowsitch et al., 2020](#)). An extension of the scripting idea was presented with the concept of orchestration. The concept of orchestration addresses the distribution and coordination of technology-supported activities on individual, group, and collective level ([Dillenbourg et al., 2018](#)), with orchestration graphs (e.g., [Prieto et al., 2018](#)) being a "notation system" for planning, enacting and analyzing multi-level, computer-supported activity systems.

Methods in the learning sciences

The methodologies and methods used in the learning sciences have been analyzed from several perspectives (e.g., [Sommerhoff et al., 2018](#); [Yoon and Hmelo-Silver, 2017](#)). According to these analyses, learning scientists have methodological roots in several disciplines, such as psychology, computer science, and science education. The different methods are often eclectically combined to address the analyses of complex processes in contexts like classrooms in schools and universities, laboratories, and informal learning contexts such as youth clubs, makerspaces ([Keune and Peppler, 2019](#)), and museums ([Lyons, 2018](#)).

The experimental paradigm has been expanded by an innovative combination with design methods coming from computer science. Design experiments ([Brown, 1992](#)) and later design research (see [McKenney and Reeves, 2021](#)) and design-based research ([Anderson and Shattuck, 2012](#); [Design-Based Research Collective, 2003](#); [Sandoval and Bell, 2004](#)) and design-based implementation research ([Fishman and Penuel, 2018](#)) have developed in response to the complexity of conditions that needed to be addressed when trying to investigate learning and teaching in authentic or real contexts. Design-based research is a cyclic methodology in which interventions are designed (and re-designed after testing their effects), mostly in collaboration with practitioners, to improve learning in real educational contexts with the equal goal to form and test theoretical advances toward understanding learning (see e.g., [Cobb et al., 2003](#); [DiSessa and Cobb, 2004](#)). One approach to advance theory on learning, in and through design research, is conjecture mapping ([Sandoval, 2014](#)), which originates from a higher-level idea about how learning could be facilitated in a particular context and moves across design conjectures (e.g., the design and how it is used) to theoretical conjectures (e.g., the outcomes

of learning and how they are observed with the design). Design-based Implementation Research (Fishman and Penuel, 2018) has developed as an extension to DBR to investigate and address the multiple questions arising from the implementation process of educational innovations in classrooms across longer periods of time and funding cycles.

In contrast to psychology and other disciplines investigating learning, units of analysis have been extended beyond the individual to include small groups or even classrooms, schools or large online communities (e.g., Stahl and Hakkarainen, 2021). These are addressed using a broad repertoire of methods, including cognitive, behavioral, and physiological measures, which either focus on individuals, interaction between individuals or their combination (see Sommerhoff et al., 2018). Besides DBR as the signature method of the learning sciences, diverse methods are employed. While case studies and classical experimentation are used frequently, methodological innovations are particularly widespread in the learning sciences. Qualitative and quantitative process analyses of “big data,” written and spoken language, of gestures, of artifacts, and of logfiles are used in these studies—and often so in combination in order to achieve a deep understanding of the mechanisms of learning and collaboration (Vogel and Weinberger, 2018) and the effects of technology for their support (Roschelle and Teasley, 1995; Koedinger and Aleven, 2007).

Think-aloud protocols and dialog analyses (see Vogel and Weinberger, 2018), as well as (social) network analyses (e.g., Oshima et al., 2012; Shaffer, 2017) are among the methods frequently used to analyze reasoning and learning in authentic settings. Logfile analyses have been used to more specifically target the interaction of learners with and within technology-enhanced learning environments. Increasingly, physiological measures like eye-tracking or heart rate variability are used to assess attentional processes and mental load in the learning process. Beyond these physiological measures, the learning sciences has been rather slow in making use of new methods from the neurosciences (see Varma et al., 2018).

Core and periphery. DBR is systematically taught in around 25% of learning sciences programs (Sommerhoff et al., 2018) and is the method of choice in an even smaller fraction of conference and journal contributions in the CSCL community within the learning sciences (Hmelo-Silver and Jeong, 2021a,b). However, the programs that teach DBR systematically seem to form a core of programs in the learning sciences community that are conceptually and methodologically more coherent, and relatively similar. Sommerhoff et al. (2018) suggest in their conclusions that this set of programs may be considered as the nucleus of an emerging discipline of the learning sciences. This nucleus is surrounded by orbiting programs that have strong roots in other disciplines. These programs in the periphery drive methodological innovation and shape the field of the learning sciences. Recent methodological developments with strong influence on the learning sciences include learning analytics (Lang et al., 2017), eye-tracking (Jarodzka et al., 2021), and multi-modal learning process analyses (Malmberg et al., 2019).

An outlook on advancing research on learning in the learning sciences

The learning sciences have produced and worked on a successful research program on individual and collaborative learning in authentic contexts in formal and informal settings over the past 40 years. This program includes new conceptual frameworks (e.g., collective knowledge construction, knowledge building, scaffolding) and new methods that were adopted from contributing disciplines and further developed to advance knowledge on learning (e.g., design-based research). Looking ahead, we highlight five fields of potential importance for the future of the learning sciences that can help to fill existing research gaps and to generate new insights to address pressing educational and societal issues. They span from (1) replicating prior findings, to (2) novel means of assessment and (3) conceptual and methodological innovation in future research, to (4) fundamental aspects related to educational equity within understanding learning and (5) personalized learning as a key focus of interest and goal within the learning sciences.

- (1) *Replicating research findings.* In its early years, research in the learning sciences was often descriptive with the aim to discover mechanisms and conditions rather than their validation through additional research. While the discoveries within the learning sciences contributed to novel perspectives on educational phenomena, topics such as replication and open science have hardly been addressed in the learning sciences. For example, there are only a few meta-analyses on learning sciences and CSCL research (e.g., Belland et al., 2017; Jeong et al., 2019) which leaves important programmatic papers (e.g., Wise and Schwarz, 2017) speculating on the state of research. The learning sciences have produced a wealth of new evidence through empirical studies. To advance the field, a more systematic examination of the robustness, replicability, and transferability of the discoveries is needed. It is currently still subject to discussion within the field whether and by which methods such investigations of robustness and transferability should be undertaken. It is conceivable that an expansion of research in the learning sciences that aims to confirm and evaluate findings across contexts is a prerequisite for systematic impact in related fields and practice (e.g., teacher education).
- (2) *Emphasis on assessment.* There is highly important work in the learning sciences that considers novel approaches to assessment that are aligned with educational perspectives central to the learning sciences (Hickey and Harris, 2021). Yet, it has not been a central focus of the learning sciences to develop new forms of assessment that are aligned with domain-specific and cross-domain knowledge and skills facilitated through problem-solving, inquiry, and design pedagogies. Better aligned assessment is needed to evaluate the effects of these pedagogies for different uses, including their formative use in classroom assessment to help students to learn, their summative use to determine individual achievement, and their use to evaluate specific interventions, programs, or institutions (Pellegrino, 2018). Given the strong focus on disciplinary knowledge and engagement (Herrenkohl and Polman, 2018) in the learning sciences, models of domain-specific competence development (Ufer and Neumann, 2018) and learning progressions (Alonzo, 2018) seem to provide good starting points for these new kinds

of assessment. Technology can play a new important role in assessment, beyond making the data collection more efficient. For example, in formative assessment, technology can be used to analyze log file data quickly to help teachers to give adaptive and process-related feedback to individuals and groups, and to adjust the level of scaffolding (e.g., van Leeuwen, 2015; Zhai et al., 2020). Ultimately, better means of assessment will be necessary for the learning sciences (i) to validate that the way learning is observed and supported within the learning sciences corresponds to their theoretical conceptions and (ii) to provide a basis for the further creation and confirmation of highly valid research findings.

- (3) *Appreciation of conceptual and methodological innovations from other disciplines.* Learning scientists differ on whether they believe they are a discipline with a common methodological core (Sommerhoff et al., 2018), an interdisciplinary group working on common projects requiring shared conceptual framework models (Wise and Schwarz, 2017), or a multidisciplinary community of researchers who mutually inspire each other through insights into their respective disciplinary research. It is likely that all three views apply, but to different groups of learning scientists (Sommerhoff et al., 2018) and that innovations from several related disciplines, which are being taken up and used, are an important driver of progress in the learning sciences. A clear example of this is the rapid development in the areas of data science in general, and educational data mining and learning analytics specifically (e.g., Romero and Ventura, 2020; Rosé, 2018; Teasley, 2019). Among others, similar innovations could be found, for example, in psychology with recent attempts to link the nomothetic (striving for general regularities) and the idiographic (explaining the individual case) research paradigms (e.g., Cook et al., 2018; Molenaar and Campbell, 2009). Taking up existing opportunities and generating new opportunities to monitor better the “innovations next door,” and to use them for learning sciences research on authentic contexts of learning and collaboration, will be of high importance for the learning sciences.
- (4) *Educational Equity.* Many learning scientists have grappled with questions of educational equity in recent years with the aim of understanding how forms of marginalization and representation relate to understanding learning and learning opportunities (e.g., Politics of Learning Writing Collective, 2017; Bang and Vossoughi, 2016; Esmonde and Booker, 2016; Uttamchandani et al., 2020). Within the work of educational equity, design has been considered as a foundational approach toward transforming social and community realities that, along the traditional aim of educational design research, contribute to theoretical approaches regarding equitable learning opportunities (Gutiérrez and Jurow, 2016). Among other things, researchers in this area ask to what extent learning materials, curricula, and pedagogies interact with learner characteristics associated with race, ethnicity, and gender. These interaction effects can systematically create and perpetuate disadvantage and the erasure of general learning effects. Moreover, knowledge about these interaction effects can also be used to support learning in specific conditions with specific measures. Empirical work related to educational equity within the learning sciences increasingly focuses on STEM and computer science learning, where diversified representation, restorative approaches, and justice-centered orientation promise more social sustainability also through the transformation of these domains (e.g., Barton et al., 2017; Vossoughi et al., 2013). Work in this area has focused on, for example, indigenous knowledges (e.g., Tzou et al., 2019; Kafai et al., 2014) as well as racial and ethnic representation (e.g., Tofel-Grehl and Searle, 2017; Holbert et al., 2020). Moreover, also LGBTQ+ issues (e.g., Uttamchandani et al., 2020) and gender equity (e.g., Buchholz et al., 2014; Keune et al., 2019) have been increasingly addressed. A crosscutting focus of this work has been transforming domain areas, inviting diverse cultural practices, and identifying relevance of cultural and community practices. For example, work with indigenous families has focused on opening up STEM practices to contribute to the socio-historical and community practices of nondominant and marginalized people in these fields through intergenerational design and storytelling (e.g., Tzou et al., 2019). While these issues have, to date, predominantly been identified within North American contexts, they have been increasingly taken as exemplary for raising pressing questions about educational equity in other countries and for addressing them with empirical research (e.g., Bang, 2019). The broader international interest in educational equity within the learning sciences has been substantiated with the formation of the ISLS Equity and Justice committee that is charged to identify and address “issues related to diverse representation, the systemic marginalization or erasure of particular voices, and justice-oriented scholarship” (ISLS, <https://www.isls.org/members/committees/>).
- (5) *Personalized learning.* Using technology to adapt the content to be learned and the instructional support to each individual learner’s current needs, both on micro and macro time scales, and to do this in meaningful social contexts is a vision in current approaches to personalized learning (see Plass and Pawar, 2020). Research projects are currently underway across the world that focus on the role of artificial intelligence in education more generally and in facilitating learning processes more specifically. The learning sciences have had a head start with decades of research on ITS, scaffolding, and CSCL in general. Strong theorizing about learning mechanisms and processes in individual and collaborative learning has made studies in the learning sciences amenable to data scientists, even beyond the often-employed well-structured domains. The algorithms used, and rapidly evolving, in learning analytics are often far superior in predicting learning outcomes based on multiple learning process measures than the mostly pure linear regression analyses that have been common in practice within the learning sciences and related educational research until now. Moreover, these approaches resonate, both with calls for educational equity and individual assessment that allow to capture processes and products as well as knowledge and skills. While there is initial evidence for positive effects of systematically employing these AI-based approaches in theory-based adaptive scaffolding environments, there are still many challenges waiting to be tackled by interdisciplinary teams of experts from the learning sciences and learning analytics (Rosé, 2018).

Defining educational neuroscience

The field of educational neuroscience has been growing since the “Decade of the brain” in the 90s, spurred by the progress in neuro-imaging methods (Pasquinelli, 2011). Educational neuroscience seeks to understand how we *learn* by looking at our behaviors, cognition, emotions and their underlying brain mechanisms. Some authors prefer to use the denomination “science of learning” (Howard-Jones et al., 2018; npj Science of Learning: <https://npjsciencelearningcommunity.nature.com/>) to highlight the evidence-based approach to learning that is at the core of educational neuroscience.

Educational neuroscience combines multiple disciplines such as biology, genetics, neuroscience, psychology, philosophy and ethology (depicted in Fig. 1). The denomination ‘Mind, Brain and Education’ particularly emphasizes the contribution of psychology and neuroscience to education. Current textbooks of educational neuroscience (Thomas et al., 2020), journals (Mind, Brain, and Education; Trends in Neuroscience and Education), research centers and conferences (Center for Educational Neuroscience; International, Mind, Brain and Education Society) embrace this interdisciplinarity. A wide diversity of methods and levels of investigation are being employed, from single-cell studies, to large-scale randomized controlled trials in classrooms. To cite but a few methods, behavioral geneticists employ genome analyses and twin studies to study genetic influences on educational achievement. Biologists and neuroscientists use Magnetic Resonance Imaging, Electroencephalography and Near-infrared Spectroscopy to study processes of change in the brain. Psychologists design behavioral studies, experiments and randomized controlled trials, to try to unpack which factors influence human learning. They also conduct observational and qualitative studies to enable an in-depth understanding of people’s attitudes, thoughts and emotions, all of which influencing the acquisition of skills and knowledge. Ethologists observe animal behaviors, because studies comparing humans, other primates and animal species allow us to understand learning in the context of evolution. Philosophers contribute to debates on how levels of description (i.e., cell, brain, individual, ecosystem) relate to each other. They propose thought experiments and challenging questioning on theoretical, methodological and ethical aspects of educational neuroscience.

Educational neuroscience can be seen as a multifaceted field where all these levels of description bring a unique perspective while contributing to a more global and complex understanding of the phenomenon of learning. Mirroring the diversity in the levels of description is the diversity in the scales of investigation. Some of the research does not involve any participants. That is the case when reflecting on the ethics of cognitive enhancement, or when debating the theoretical definition of “learning” or “thinking processes”. In contrast, some international studies, such as those investigating how phonics training aids literacy acquisition across different languages, involve thousands of participants. In between these two extremes, there are case studies with two or three participants, small scale qualitative focus groups, behavioral studies involving hundreds of participants, or large-scale randomized controlled trials. Each scale of study is informative.

Fig. 1 The multiple disciplines comprising educational neuroscience.

Fig. 2 Children's learning takes place within multiple circles of influence. The white arrow reflects bidirectional influences between circles. Taken from Thomas et al. (2019) [Open access article: <https://doi.org/10.1111/jcpp.12973>].

Using all these methods, educational neuroscience addresses the multitude of factors that influence learning. These factors can be seen as the interaction of different nested ecosystems, where the child is subject and actor within the school, family, society and governmental systems, as depicted in Fig. 2.

This article has three parts. In the first, we present some of the key research domains of educational neuroscience: brain health, social and emotional learning, executive functions, and individual differences in learning. We illustrate how they contribute to an understanding of learning processes within social contexts, and can inform the work of educators. For some, reviewing these domains of research questions the relevance of neuroscience as a discipline that would bring a new perspective above and beyond the professional knowledge of educators, and the well-established theories in psychology. In the second part, we give a flavor of this debate and present several arguments on the added value of neuroscience. We highlight the importance of collaborative projects involving interdisciplinary researchers and educators to generate knowledge that is both robust and impactful. In the third part, we suggest two core areas of development in educational neuroscience that could be taken forward by a new and talented generation of researchers and educators.

Key research domains in educational neuroscience

Brain health fundamentals

For students to be able to learn, they first need to have their basic physiological and social needs met. We will start by presenting some brain health fundamentals (nutrition, exercise, sleep, and protection from stress), whose mechanisms have been further unraveled by educational neuroscience.

Nutrition

Nutrition is fundamental to grow “a healthy mind in a healthy body.” There are several pathways through which food impacts brain functioning and development ([Center for Educational Neuroscience, 2016a](#)): (1) via an increase in blood glucose and energy available to the body, (2) via the release of neurotransmitters, related in part to the consumption of carbohydrates and proteins, and (3) via the provision of micronutrients. On a global scale, there is still progress to be made for children to have appropriate levels of nutrition. Twenty-two percent of the children under 5 in the world experience stunting, meaning that they suffer from growth impairment, in part due to poor nutrition ([UNICEF et al., 2021](#)). Stunting is associated with suboptimal social, cognitive and motor development ([Perkins et al., 2017](#)). At the other extreme, 5.7% of the children under 5 are overweight ([UNICEF et al., 2021](#)).

Exercise

Physical education lessons and physical games during recess time might not be the first activities we think about when it comes to learning at school. Beyond its intrinsic value as a joyful and relaxing activity (for some), physical exercise is associated with better cognitive and academic performance across the lifespan ([Hillman et al., 2008](#)). Exercise seems to stimulate the proliferation of neurons and communication between neurons (via an increase in the brain-derived neurotrophic factor) ([Stillman et al., 2020](#)). Comparisons between participants with different levels of physical activity also suggest differences in brain networks involved in the allocation of attentional resources, in the monitoring of errors and resolution of conflicts ([Hillman et al., 2008](#)). Exercise might also help children sleep at night, offering additional benefits for the learner.

Sleep

Sleep facilitates the learning and consolidation of new information. Fully rested learners are better able to pay attention and keep information in mind, as shown in an experimental study which voluntarily induced sleep deprivation in teenagers ([Lo et al., 2016](#)). Whereas sleep deprivation can negatively impact performance, small adjustments in the school system such as shifting the start of school by an hour are associated with positive changes in school performance, especially for teenagers ([Dunster et al., 2018](#)). Neuroscience and biology have allowed researchers to explore the fascinating mechanisms through which sleep helps the brain learn and memorize information. Information that has been newly encoded by learners is reactivated at night, following an active process of consolidation which helps to form long-term memories ([Rasch and Born, 2013](#)). Measures of brain activity have led researchers to investigate whether it is the total amount of sleep and/or the quality of sleep that is related to performance ([Hayes and Bainton, 2020](#)). Either way, protecting sleep from external stressors is important.

Protection from stress

Protection from chronic stress is essential for children to feel safe, and to free their emotional and cognitive resources for positive learning activities. Stressors can be physical, such as noise and pollution, or social (threat, conflict). Poverty, parental job instability, abuse, and trauma can all induce long-term stress with detrimental consequences for brain development. Stress increases blood pressure, heart rate, blood sugar and hormones such as cortisol ([Center on the Developing Child at Harvard University, 2021](#)). Animal studies have shown that increased cortisol is associated with alterations in the volume of the amygdala (involved in emotional processing), in the hippocampus (involved in memory processing) and with the atrophy of neurons that are essential for the communication between the prefrontal cortex and other brain regions ([Blair and Raver, 2016](#)). The prefrontal cortex is a key brain area involved in planning, attention, and self-regulation. Children exposed to prolonged stressors, whose energy is all focused on responding to stress, can have difficulties in regulating their attention and behavior in learning contexts. Stressors go beyond the school walls, and trauma and abuse require specific integrated interventions. With that in mind, several strategies have been identified to reduce stress in educational environments. These include: reducing physical stressors in the environment (e.g., noise), reappraising learning (e.g., presenting learning tasks in a way that plays to children's strengths), using breathing techniques, mindfulness, recovery times, and physical exercise ([Whiting et al., 2021](#)). Stable and supportive relationships also help mitigating the effect of stress on children.

Social and emotional learning

Educational neuroscience has reinforced the view that learning is a social and emotional process ([Immordino-Yang et al., 2018](#); [Immordino-Yang and Damasio, 2007](#)). In his seminal work, Antonio Damasio questioned the role of a “cold” and “emotionally neutral” reason that would guide our behaviors and decisions ([Damasio, 1994](#)). He showed that emotions are critical for decision making, because they allow us to process certain types of behaviors as rewards or punishments, and to weight risks and benefits. Complex emotions such as guilt and shame, for example, drive us to socially acceptable behaviors.

Damasio's studies in the 1990s were with neurologically impaired patients, who suffered from lesions in the frontal lobes and showed difficulties in social adaptation (Damasio et al., 1994; Eslinger et al., 1992). Neuroimaging studies with non-clinical patients further helped researchers to map out the brain regions that are involved in reasoning and decision making, confirming Damasio's findings. The frontal lobe, which often has been overly simplified as the area of "rationality," constantly interacts with the brain regions from the limbic system which are processing emotions, rewards and memories (Dumontheil and Mareschal, 2020). The orbitofrontal cortex maps out the associations between actions and their expected rewards. It is connected to the amygdala (which processes a wide range of emotions such as fear, disgust, love), and to the striatum (which processes rewards). The ventromedial prefrontal cortex, particularly important to making decisions in social contexts, is connected to the amygdala and to the hippocampus, which stores memories of our sensory experiences in different situations.

Understanding how social and emotional processes influence our reasoning and decision making has the potential to inform education by giving insights into what motivates and hampers students' learning. Adolescence is a key period of development for social cognition, including domains such as recognizing and expressing emotions, processing emotional rewards, understanding the perspective of others, planning, and controlling one's behaviors (Blakemore, 2010). This development is noticeable both in adolescent behaviors and in the protracted development of their prefrontal cortex. Adolescents are particularly sensitive to social approval from their peers (Tomova et al., 2021). This can have negative consequences, for example when substance abuse, or risky driving, are seen as valued within their peer group. However, a high sensitivity to social rewards also means that teenagers can be more prone to act prosocially if their peers do so (Tomova et al., 2021). In the context of classroom learning, organizing collaborative learning activities with structured, social feedback could be a way to recognize and harness adolescents' sensitivity to the opinion of their peers. Presenting adolescent role models could also favor students' engagement in learning activities.

Moving beyond a focus on performance *per se*, and considering the role of social and emotional processes in learning prompts us to create learning contexts that are socially and emotionally nurturing for students. It is not only about what students can do, and how fast they can do it, but how they learn, with whom, and what motivates them to engage in learning activities.

Executive functions

With that in mind, we can consider how individuals regulate their behaviors and their emotions during learning, and how they manage to focus and plan ahead to achieve their goals (Diamond, 2013). These skills are referred to as "executive functions" and include: (1) inhibition (i.e., the ability to control one's attention, behavior, thoughts, emotions, rather than acting on impulse or automatically in response to external stimuli); (2) working memory (i.e., the ability to keep information in mind and work with it); and (3) cognitive flexibility (i.e., the ability to change perspective and switch from one task to another) (Diamond, 2013; Miyake et al., 2000). They underpin academic achievement in a variety of domains (mathematics: Cragg and Gilmore, 2014; Lubin et al., 2013; science: Mareschal, 2016; reading: Cain et al., 2004). In the classroom, student's executive functions are at play when teachers implement behavioral management strategies, try to redirect attention on a task, or set up a debate.

Systematic research can help to better understand which tasks and contexts are particularly challenging for students' executive functions, and the age at which vulnerabilities are present, with the view to facilitate learning processes. Classrooms are filled with multisensory distractors, such as visual displays on the walls (Fisher et al., 2014) or background babble (Klatte et al., 2013; Shield and Dockrell, 2003), which place extra demands on students' executive functions. Children who report having greater difficulties in switching from one task to another report being more distracted and annoyed by noise in the classroom (Massonnié et al., 2020a). This shows the need to pay attention to the *physical* characteristics of the learning environments (Montazami et al., 2015). Distractions are not the only aspects of a classroom environment which are challenging for executive functions. Long instructions can also be difficult for students, who have to retain all the information provided by the teachers while also doing what is expected of them. Breaking down tasks and instructions into smaller components, simplifying the linguistic structure of verbal material, and using memory aids, can all be helpful (Gathercole and Alloway, 2007).

Younger children are particularly sensitive to the demands placed on executive functions, as these skills and their associated brain areas undergo protracted development during the school years. Younger children might need more scaffolding to succeed at specific tasks, such as a breakdown of instructions into smaller steps. They can also be particularly distracted by background speech and classroom noise, especially if they have difficulties inhibiting distractors (Massonnié et al., 2019). Paradoxically, classrooms in the early primary school years tend to be the noisiest (Picard and Bradley, 2001). Children are less able to inhibit the impulse to communicate at an age when they are also less able to screen out the distraction of other children's communication.

Research exploring executive functions has sometimes been associated with hype around training these skills via interventions such as computer training, mindfulness, or martial arts (Diamond and Ling, 2016; Diamond and Lee, 2011). However, there is currently little evidence that training on a given task requiring executive functions improves performance in other unrelated skills (so-called "far transfer"): children just tend to improve at the skills they are trained on (Kassai et al., 2019). If children are trained to hold more numbers in memory, they might be able to hold more numbers, perhaps also more words in memory, but they might not be better at all sorts of maths or science exercises. Promising interventions, such as the Unlocked project (Roy et al., 2019), look at *domain-specific* training of executive functions, that is, training that is embedded in the domain in which they are to be applied, such as science or mathematics. Another promising approach is for interventions to target: (a) children's overall conduct at school and/or (b) their confidence and motivation to exert self-regulation, which might have a snowball effect on their overall attentional focus in class' (Ng-Knight et al., 2021). When considering the impact of educational interventions, it is important to remember that children's ability to take advantage of specific pedagogical practices may, to some extent, depend on other properties of their environment, such as their socioeconomic background, and also on their genetic make-up. Educational neuroscience research has investigated both influences.

Socioeconomic status and educational outcomes

Policymakers are particularly concerned about gaps between children's educational outcomes, and one factor associated with these gaps is socioeconomic status (SES). SES reflects many facets of a child's environment, including material and financial resources, educational opportunities, power and social prestige (Hackman and Kraemer, 2020). Children coming from high SES backgrounds score more highly in tests of oral language, executive functions, reading and mathematical skills, which is likely to be reflected in their social interactions and educational success in the long run.

There are multiple factors explaining the associations between SES and children's outcomes (Evans, 2004; Farah, 2017). Children from low SES background are more likely to be exposed to adversity, which brings stress, threats and violence, and is detrimental to learning and emotional regulation. They also tend to be more exposed to noise and crowding within their home, which can disrupt sleep and induce distraction when learning. Access to health services and quality schools might be more difficult in areas of disadvantage, and family SES influences the types and number of educational resources available in the house, such as books and toys. Additionally, parents facing stressful financial or professional situations might find it difficult to be responsive when interacting with their children (Hackman and Kraemer, 2020).

However, it is important not to consider the relationships between early adversity and children's outcomes purely in terms of deficits and to take into account the strengths and adaptability these children might develop in non-academic areas of their life. Children experiencing adversity might be better able to detect threats, identify negative emotions, understand uncertainty and might be skilled at choosing whom to trust (Ellis et al., 2020). Children coming from low-SES families might also use different strategies to solve the same problems as their peers coming from a higher SES background (Hackman and Kraemer, 2020). Comparisons across SES environments and cultures suggest that the additional challenges in low SES environments may in some case stimulate advances in executive function skills (Howard et al., 2019).

Supporting families living in areas of disadvantage is essential to offer the best educational experience for children and to reduce SES disparities in achievement and learning opportunities. The multitude of pathways through which SES can influence child development allows consideration of various routes for support. Interventions can focus on financial resources with income support and cash transfer programs, which might help accessing schools, buying educational material and reducing income-related stress (Troller-Renfree et al., 2022). Free educational resources might support positive parent-child interactions (<https://wordsforlife.org.uk/>, Dockrell et al., 2020), and classrooms can work to provide a stress-free environment sensitive to children's individual needs and skills (Whiting et al., 2021). The combination of many small effects can lead to big effects on child development.

Individual differences in educational outcomes: genetics

Educational neuroscience has fed long-standing debates about how nature and nurture shape human learning experiences. The field of genetics has been the subject of both public interest and concerns, perhaps due to its potential to "profile" children and outline individual differences early on in life. Researchers have assessed the extent to which genetic make-up—whether indexed by degree of relatedness in identical versus fraternal twins or by direct measures of DNA variation—predict educational achievement (Lee et al., 2018). Genetic factors are indeed associated with school attainment (Donati et al., 2021; Lee et al., 2018). However, associations are complex: variations in multiple genes (perhaps thousands) are associated with a given competence, such as reading, and these genes are not entirely specific to reading, but are involved in other abilities. So, we cannot identify "the gene for intelligence" or "the gene for mathematics."

Furthermore, both genetic and environmental factors interact (and sometimes align) to influence children's learning outcomes. If a child from a family of passionate readers is thriving at school, getting their hands on every book available, it might be that they have inherited relevant genes from their parents. It might also be that they are raised in an environment where a lot of books are available, and where family members are encouraging reading practices by showing their own enthusiasm for books, or by organizing reading sessions.

The environments which children experience influence how, and to what extent, their genetic background is expressed. In that sense, genetic effects are not deterministic. Let us simplify the picture and establish that, based on their genetic profile, some children are more likely to be good readers than others. If their environment provides no reading opportunities (e.g., there are no books), this potential will not be expressed. None of the children will be an avid reader. In contrast to this group, children who do benefit from support from their environment (e.g., accessing books and libraries) would fare better, irrespective of their genetic background. It is only in an educational environment where a multitude of children are provided with learning opportunities (e.g., they are surrounded by books and introduced to reading) that individual differences based on genetic background will become salient. In sum, although children are born with a particular biological and genetic background, their environment determines how much of this potential is expressed. The goal of current research is, ultimately, to unpack the causal pathways by which environmental and genetic influences shape child development and educational achievement, to personalize education and offer the best support possible (Hart, 2016).

The five (non-exhaustive) areas of research we have reviewed in this section (brain health fundamentals, socio-emotional learning, executive functions, socioeconomic status and individual differences in genetic background) help to shed light on the complex ways by which the family, classroom and social environments influence children's learning experiences. We now move on to consider some of the debates that have been stimulated by the dialog between education and neuroscience.

Translating educational neuroscience research to education

What does neuroscience bring above and beyond what educators and psychologists already know?

There has been much debate as to whether neuroscience brings anything beyond what educators and psychologists already know. Some argue that neuroscience is merely re-establishing principles well known in psychology, or involving costly methods that do not bring new insight (Bowers, 2016; Dougherty and Robey, 2018). If teachers are dealing mainly with students' behaviors (i.e., what they say, what they demonstrate they know and do not know in assessments), do they need to know about brain processes?

First of all, re-establishing what educators already know is not a bad thing in itself. Converging evidence in educational neuroscience shows that sleep is important, and that chronic stress is deleterious. Neuroscience evidence has a "seductive allure" which can attract further attention from the media. When messages are backed up by robust neuroscience evidence, they can encourage decision-making in important areas such as the protection of sleep and the reduction of stressors in the environment. However, the "seductive allure" of neuroscience can also be a double-edged sword when neuroscience (or merely its trappings) are misapplied (e.g., when advertising products that are not evidence-based, Beck, 2010).

Importantly for educational practice, there are cases where what we think we already know is actually *not* backed-up by science. False beliefs about brain and learning processes, called "neuromyths," can have consequences for learning conditions. A seminal study from 2014 showed that more than 90% of the teachers from five different countries believed that individuals learn better when they receive information in their preferred learning style, an idea that is not backed-up by scientific research (Howard-Jones, 2014). Implementing teaching strategies based on "learning styles" might be unhelpful, categorizing students and reducing the range of learning opportunities available. Neuromyths about neurodevelopmental disorders (e.g., if a child responds to stimulant medication such as Ritalin, then they are likely to have Attention Deficit Hyperactivity Disorder) are also held by some educators and members of the general public (Gini et al., 2021). Tackling these myths would help to reduce stigma and to provide better support to learners. Another misconception is the idea of "multitasking." Research in educational neuroscience brings nuance to this idea, by suggesting that we are not deliberately paying attention to two things at the same time but instead constantly switching from one task to the other (The Learning Scientists, 2016). More awareness of this switching process can help to reduce cognitive load in the classroom by minimizing demands to "multitask." For more information on "neuro-myths" and "neuro-hits," see Center for Educational Neuroscience (2016b).

Neuroscience does more than proof-checking common sense when it helps to understand *how* we learn—investigating mechanisms. To take one example, teachers know that it can be challenging to teach some scientific concepts because they are counter-intuitive. Advances in scientific theories come from questioning our intuitions and commonly held theories (Kuhn, 2012), following a process called conceptual change. Teaching children that the world is round not flat, contrasts with their intuitive understanding from everyday experience (they walk on a flat floor). We know that scientific understanding does not completely replace or overwrite previous ideas. Instead, multiple ideas and theories are available to children who must acquire the relevant executive function skills to apply the new concepts in the contexts in which they are appropriate. For example, they will use the idea that the Earth is round when doing science tests or watching satellite images, but they can focus on the feeling of a flat surface when playing football. Neuroscience has revealed that learning new scientific concepts and inhibiting pre-existing beliefs is associated with brain areas involved in the detection of conflict (the anterior cingulate cortex), attention, inhibition, working memory and the integration of information (within the prefrontal cortex) (Mareschal, 2016). Houdé et al. (2000) suggested that a shift operates from perceptual to more analytical learning strategies when learning scientific concepts. This is based on a shift in cerebral activity from posterior to more frontal areas. An understanding of mechanism points to interventions that may help the learning of counterintuitive scientific concepts – namely improving inhibitory control skills (Roy et al., 2019).

Finally, beyond validating and refining theories from other fields, neuroscience helps generate new hypotheses to understand phenomena such as, for example, learning difficulties. Neuroscience can suggest where to look by giving an insight into impaired neural functions, and by comparing the neural circuits recruited by students who experience, and those who do not experience, difficulties—see Gabrieli (2016), Ramus (2014) for an illustration with dyslexia and Howard-Jones et al. (2016) for dyscalculia. A biological understanding of the brain and of neural mechanisms also constrains predictions that can be made about interventions (Howard-Jones et al., 2016). For example, if neural networks are domain specific, then training a specific ability will not generalize to another ability, constraining the possibility of far transfer (Thomas, 2019).

Educational values are not defined by educational neuroscience

Perhaps a reassuring stance for the skeptics is to remember that research findings in no way aim to be prescriptive (Willingham, 2009). Educational values are defined independently of science—what we decide to value in education is a choice of society, whether it is rote memorization, creativity, collaborative learning, or any other priority. To give an example, the international definition of 21st century skills, which include communication, collaboration, creativity, critical thinking, and learning to learn, echoes the need of learners to adapt to a fast-evolving job market and to be critical consumers of technologies (UNESCO Office Dakar and Regional Bureau for Education in Africa and Brookings Institution, 2020).

The precedence of the social system can be seen in sleep research. Research demonstrates changes in circadian rhythms from the primary school to the high school years. Adolescents often go to bed later but starting times at school are the same across grades, if not earlier in the higher grades (Carskadon, 2011). This means that, in effect, adolescents experience mild but cumulate sleep deprivation across the school week. There is promising research showing the benefits of starting school later for adolescents' sleep and

school results (Dunster et al., 2018). However, interventions are difficult to implement (Education Endowment Foundation, 2019) given that the start of school is tied to other social and economic factors such as parents' working hours.

Collaborations between educators and researchers are essential because educational neuroscience does not aim to be prescriptive. Rather, it aims to inform learning processes with the potential to be applied to the classroom, depending on the strength of evidence and on pedagogical priorities. It aims to provide a wider set of tools and methods for educators to fulfill their educational goals.

Collaborative projects between scientists, educators and learners are essential

Educators manifest interest in educational neuroscience and its potential application to the classroom (Simmonds, 2014), which can lead to the development of truly collaborative projects in which educators are participating in the design, implementation, and dissemination of research findings (Massonnié et al., 2020b). Collaborations with teachers have grown over the years with the idea that carrying out research *in* schools is not enough for it to inform practice: rather, research must be *with* schools. For translation to happen, the "why" and "how" of research must be sensitive to the reality and complexity of learning contexts, in which educators are the experts.

Teachers are shaping learning environments and have a key understanding of which factors influence learning in the classroom. Differences in terminology and methods between teachers and researchers might create challenges in collaborations (e.g., teachers might talk about "concentration" when researchers talk about "attention"). These can be overcome with open discussions, trust, and familiarization to the concepts and practices from the other field (Hobbiss et al., 2019). Researchers might not be aware of all the constraints faced by educators and truly collaborative projects might require extra flexibility. Some very useful practical guidance for school-based research has already been compiled (Plummer et al., 2014). Detailed and practical guidance on research methods has also been created for teachers (Churches and Dommett, 2016). Establishing a common ground goes beyond the "facilitation" of research projects, it can ultimately lead to more impactful projects answering social needs.

It is worth noting that not *all* neuroscience projects related to learning need involve educators or take place in naturalistic settings. In some senses, basic research remains a foundation upon which translation is built. Matusz et al. (2019) have proposed a model with three-stages of research, namely: (1) Classic laboratory research, with maximal control over stimuli and the environment to isolate very specific factors influencing learning, (2) Naturalist laboratory research, involving more dynamic and complex settings with some control on the environment, and (3) Fully naturalistic research. Each stage has its own advantages and inconveniences, and all three would ideally be implemented. Tools assessing the degree of ecological validity of a study might help in this endeavor (Naumann et al., 2021). We will now highlight two main ideas to move the field forward: a systematic training for researchers on interdisciplinarity and collaborations with educators, and the involvement of learners in the research process.

Where does the future of educational neuroscience lie?

Training researchers for interdisciplinarity

Educational neuroscience is a challenging field of research requiring both a strong expertise in its constituting disciplines and a capacity to gain perspective on their integration and application to education. This creates strong expectations for early career researchers working in the field of educational neuroscience, for previous generations of researchers who might have been specialized in one specific discipline, and for both generations to develop two-way collaborations with educators and educational stakeholders.

University programs have been created as early as in 2002 (Blake and Gardner, 2007; Harvard Graduate School of Education, 2021; Birkbeck University of London, 2021; Ecole Normale Supérieure, 2021; Universität Osnabrück, 2021) with the view to instigate interdisciplinarity by building expertise in multiple disciplines of educational neuroscience. In addition, mentoring schemes and peer support groups can help maintain and develop interdisciplinarity within the research community (Gotlieb et al., 2019).

However, collaboration needs to go beyond the walls of the university to truly inform learning in naturalistic contexts. Place-ments in schools and involvement in learning communities would provide invaluable opportunities to gain insight into the objectives, and working conditions of educators. Yet, it is still rarely done due to administrative and financial challenges as well as the flexibility required from both universities and schools to build synergies. Valuing time in school as part of the professional development of academics would be a great step forward to foster impact and knowledge exchange (Glennon et al., 2013).

Involving learners in the research process

So far, most of the endeavors related to knowledge exchange, dissemination and impact have focused on teachers as the gateways to educational settings and key providers of learning opportunities. However, one further step needs to be taken to involve the learners (Brookman-Byrne and Commissar, 2019). If we are to study learning processes, learners are the ultimate beneficiaries of the research. Dissemination outlets already exist for learners of different ages, as shown by initiatives such as the podcasts series from the Learning scientists (The Learning Scientists, 2022) or the collection "Everything you and your teacher need to know about the brain" published in Frontiers for Young Minds (Peters et al., 2020).

Introducing children to brain and learning processes can change their views on how the brain works, both in terms of its functions and its components (Chauvin et al., 2019; Marshall and Comalli, 2012). Explaining neuroplasticity (e.g., the fact that neuronal connections change in the process of learning) has the potential to increase students' motivation, although links to academic achievement are inconsistent (Sarrasin et al., 2018). Beyond sharing conceptual knowledge about learning and the brain, educational neuroscience has the potential to empower students in using evidence-based learning strategies (e.g., Dunlosky et al., 2013) and in taking care of their brain by considering, for example, their sleep patterns, nutrition, drug and alcohol usage. Students are in the premier position to enact learning processes, yet little research has been done so far on how advances in educational neuroscience influence their behavior, learning and well-being.

Furthermore, the direct involvement of learners in the design and creation of research projects is still rare. If educational neuroscience aims to support and improve learning, it is fundamental to incorporate the learners' views on the research project: Does the project have the potential to be impactful? Can it change learning conditions or attitudes towards learning? Can it support the learners' growth and development? (van Atteveldt et al., 2019). To go one step further, students can also suggest which research questions are to be investigated by academics (Tokuhami-Espinosa, personal communication, January 23, 2020). Some institutions such as the Center for Research and Interdisciplinarity (2021) in France are pairing classrooms with a scientific mentor to develop bespoke research projects. By combining innovative and impactful ideas with rigorous and ethical research methods, participatory research has the potential to energize the field of educational neuroscience while ensuring it serves the greater good (Kuriloff et al., 2009).

Conclusions

Educational neuroscience is a recent and growing field which combines the expertise from various disciplines to understand learning processes, and investigates how this developing knowledge might translate into educational practice. Educational neuroscience offers insight into many of the mechanisms influencing learning (including nutrition, exercise, sleep and stress, social interactions and emotional responses) and helps to explain individual differences between learners. Each discipline within educational neuroscience brings a unique perspective to shed light on the complexity of learning processes, and offers explanations of learning mechanisms at different levels (including the genetic, neural, and psychological levels). As such, collaborations between researchers of different fields are at the core of educational neuroscience. Collaborations between researchers, educators and the learners themselves are also critical to develop a comprehensive approach which includes not only laboratory studies but also controlled experiments and naturalistic studies in educational environments. Co-constructing research protocols with the learners themselves is relatively new and holds promise for the future development of the field. For learners are not only the recipients of educational opportunities, but full actors in their own development.

Introduction

Concepts held in human long-term memory are the basic building blocks of thought because they constitute the meaning of objects, events and abstract ideas (Kiefer and Pulvermüller, 2012; Kiefer and Harpaintner, 2020). Concepts are also crucial for language by establishing semantic meaning of words (Jackendoff, 1990). Concepts therefore play an important role in object recognition, problem solving and verbal communication (Humphreys et al., 1988; Levelt et al., 1999). Despite this general agreement about the function of concepts, the nature of human cognition has been subject of a debate in the current cognitive sciences, but also in philosophy for more than 2000 years. This debate concerns the fundamental question, whether human cognition, including concepts held in memory, is abstract and detached from perception or action, or whether it is essentially based on re-activations of perceptual and motor experiences, so-called modality-specific representations.

This debate dates back to the ancient Greek philosophers more than 2000 years ago (for an overview, see Runes, 1962; Kiefer and Pulvermüller, 2012): Since the early days of Platon, philosophers have speculated whether or not concepts are essentially grounded in our senses and in our actions with the environment (Markie, 2008). Platon and more modern philosophers such as Descartes, Leibnitz and Kant were very skeptical in this regard. According to their rationalist views, concepts are mental entities fundamentally distinct from sensory impressions. In fact, perception is even thought to require concepts as an a priori condition. According to this rationalist view, concepts are based upon innate categories or are formed by reasoning. Rationalist philosophers argued that concepts cannot reflect sensations because perception is too unstructured, in order to provide the basis for meaningful concepts. In contrast, Aristotle and more modern empiricist philosophers, including Locke and Hume, proposed that all concepts are derived from sensory experiences (impressions) and ideas, which are faint copies of impressions. Because any significant knowledge is to be gained ultimately from one's sense-based experience, concepts based upon reasoning cannot, in this view, provide valid information about the physical and social world.

A similar debate regarding the role of sensory and motor experiences for cognition has been taking place in the cognitive sciences. In the cognitive sciences, concepts are traditionally specified as abstract mental entities, different from the perceptual or motor brain systems, similarly to the rationalist philosophical stance (Quillian, 1969; Anderson, 1983; Tyler and Moss, 2001; Pylyshyn, 1984): Sensory or motor features of objects and events are transformed into a common amodal representation format, in which original modality-specific information is lost.

In contrast, similarly to the empiricist stance, embodied cognition theories assume that conceptual representations are essentially rooted in modal experiential information (Kiefer and Pulvermüller, 2012; Barsalou, 2008; Kiefer and Spitzer, 2001; Pulvermüller and Fadiga, 2010; Lakoff and Johnson, 1999; Bermeitinger and Kiefer, 2012; Kiefer and Harpaintner, 2020; Meteyard et al., 2012). According to embodied cognition theories, activity in brain systems involved in perception, introspection and action necessarily contributes to conceptual meaning. Although the terms "grounded cognition" and "embodied cognition" are frequently used interchangeably, these terms occasionally refer to slightly different classes of theories, depending on the precise theoretical stance (Kiefer and Harpaintner, 2020). While some embodied cognition theories confine experiential information to the sensory-motor systems, grounded cognition theories are typically broader and also consider the relevance of experiential information based on introspection and emotional states, that is perception of internal states.

Furthermore, strong embodied cognition theories assume a complete functional and neuroanatomical overlap between sensory-motor and conceptual processing, including mandatory activation of primary sensory-motor brain areas (Meteyard et al., 2012). In contrast, weaker embodied cognition theories and grounded cognition theories propose a partial overlap between sensory-motor and conceptual processing (for further differentiations between grounded and embodied cognition theories, see Kiefer and

Barsalou, 2013; Kiefer and Harpaintner, 2020). Accumulating evidence speaks against strong variants of embodied cognition theories but supports weaker embodied or grounded cognition theories (see discussions in Popp et al., 2019a,b; Meteyard et al., 2012). We return to this issue later in this article. For the purpose of this article, we use the terms “embodied cognition” and “grounded cognition” exchangeably to refer to theories, which emphasize the relevance of modal experiential information including internal states and emotion for cognition.

This debate about the role of sensory-motor experiences in the cognitive sciences is echoed by similar considerations in child development and education (Kiefer et al., 2022). According to Piaget’s theory of cognitive development, children acquire knowledge through sensory experiences and the manipulation of objects until the age of two. After learning to use symbols (e.g. words, pictures) to represent and think about objects and events, children are thought to develop logical thinking, which is still based on concrete events between the ages of 7 and 11 (Piaget, 1952). Formal logical thinking detached from sensory-motor experiences, the highest level of cognition, is assumed to develop later during adolescence. According to Piaget’s theory, formal logical thinking replaces thinking based on sensory and motor processes (Inhelder and Piaget, 1958). At this final stage of development, thought operations do not need to relate to concrete experiences and phenomena. The question whether this theory holds is of high relevance for the design of school lessons. At present, teachers often follow the implications of Piaget’s model: In primary schools, discovery learning and experiential learning activities are common instructional strategies for active learning arrangements. In contrast, in secondary schools these teaching strategies are less common. Often they are limited to active phases in natural science classes (if they occur at all). Sometimes, teachers even assume that experiential learning activities at secondary schools might be detrimental for an optimal development of abstract logical thinking in their students.

In order to illustrate the implications of these issues for education, consider a classroom situation, in which a teacher wants to introduce a certain type of tree, a beech, to her or his students. She or he has several possibilities for teaching the relevant information. For instance, (i) the teacher can verbally describe the shape of this tree, the color of the leaves, the texture of the bark, the use of the wood, etc. (ii) The teacher could show a movie of the physical properties and the use of a beech. (iii) The teacher could take the students to the forest where they can see a beech, can collect leaves or wood pieces and can touch the bark. They could additionally go to a carpenter’s shop, where they can observe the construction of furniture out of beech wood and where they can construct an own piece. In this latter case, perceptual and motor information elicited by the direct experience are the basis of knowledge building. The different methods to teach a beech may be differentially efficient in supporting learning. The question arises, whether research in the cognitive sciences can provide evidence, which methods has the most beneficial effects and why (Kiefer and Trumpp, 2012; Kiefer et al., 2022).

From amodal over embodiment to hybrid theories of conceptual representations

Psychological and neuroscientific research provides information on the relationship between sensory-motor processes and cognition. At the heart of the past and the current debates is the question, whether or not cognition is essentially grounded in our senses and in our actions with the environment (Markie, 2008). As outlined above, cognition has been thought for a long time to involve neuro-cognitive systems that are different from the perceptual or motor brain systems and code knowledge in an abstract amodal format, in which original modality-specific sensory-motor information is lost (Quillian, 1969; Anderson, 1983; Tyler and Moss, 2001; Pylyshyn, 1984). This theoretical account resembles the stage of formal logical thinking in Piaget’s classical theory (Inhelder and Piaget, 1958).

At a neuroanatomical level, amodal conceptual representations are assumed to be held in heteromodal association cortex such as the anterior temporal (McClelland and Rogers, 2003; Rogers et al., 2004) or posterior temporal cortex (Hoffman et al., 2012), so-called semantic hubs. Activation of modality-specific sensory and motor representations during language comprehension or conceptual thinking is considered in these class of theories only as an auxiliary process after the amodal concept has been accessed, due to imagery (Machery, 2007) or passive spreading of activation to input or output levels (Mahon, 2015).

Challenging this classical view, recent theories of embodied cognitions propose close links between the sensory and motor brain systems on the one hand and cognition on the other hand (Barsalou et al., 2018; Kiefer and Barsalou, 2013; Kiefer and Harpaintner, 2020; Pulvermüller and Fadiga, 2010; Lakoff and Johnson, 1999; Kiefer and Trumpp, 2012). Cognition and thinking is critically based on a reinstatement of external (perception) and internal states (proprioception, emotion and introspection) as well as bodily actions that produce simulations of previous experiences. These simulations of previous sensory-motor experiences (Kiefer and Barsalou, 2013) are often unconscious, but can be measured with behavioral or neuroscientific experimental techniques (Trumpp et al., 2013).

Most recent evidence suggests an interplay between modality-specific, bi- or trimodal, multimodal and amodal semantic hub regions, giving rise to the development of so-called hybrid theories (Kiefer and Harpaintner, 2020; Kuhnke et al., 2020; Patterson and Ralph, 2016; Popp et al., 2019a). Modality-specific and multimodal regions presumably represent conceptual feature content (Kuhnke et al., 2020), whereas semantic hubs code conceptual information in an overarching supramodal fashion (Binder, 2016). Most likely, a hierarchy of processing circuits ranging from lower-level modality-specific cortex over multimodal regions up to top-level amodal areas in heteromodal cortex, indexing increasing levels of abstraction, establishes conceptual representations (Kuhnke et al., 2020; Kiefer and Harpaintner, 2020).

In the next sections, we provide a comprehensive overview of the latest research on embodied cognition in several cognitive domains and discuss important implications for learning and teaching.

Embodiment of conceptual memory for objects

Concepts stored in semantic long-term memory (Tulving, 1972) code the sum of our sensory and motor experiences with the environment in a categorical fashion (Kiefer and Pulvermüller, 2012). For instance, the concept “beech” includes the information that a beech has a trunk, has branches, has leaves, the wood is used for carpentering, etc. Embodied cognition theories predict that concepts, the constituents of thought, are rooted in perception and action. Brain activation studies (for an overview see, Kiefer and Barsalou, 2013; Kiefer and Harpaintner, 2020) have provided converging evidence on the differential involvement of sensory-motor brain areas in the processing of words and concepts of different kinds (e.g. vision-related concepts vs. action-related concepts). They demonstrated activation in sensory-motor brain areas in a range of conceptual tasks (e.g. Hoenig et al., 2008; Simmons et al., 2005). In fact, conceptual and perceptual processing functionally and neuroanatomically overlap in sensory brain regions (Kiefer et al., 2008): Visual recognition of words denoting objects, for which acoustic features are highly relevant (e.g. sound-related concepts such as “telephone”), ignited cell assemblies in auditory brain regions that were also activated by sound perception. Processing of action words (e.g. “to throw”) elicited activity in motor areas (Hauk et al., 2004), partially overlapping with activity induced by real movements of the corresponding limb (e.g. hand-related movements). Similarly, picture of appetizing food or words related to smell (“cinnamon”) activated regions in the brain associated with gustation and olfaction (Simmons et al., 2005; Gonzalez et al., 2006).

More recent fMRI studies (Kuhnke et al., 2020; Popp et al., 2019a), however, indicated that not only modality-specific brain areas, as defined by localizer tasks (e.g. acoustic localizer: listening to sounds; motor localizer: moving the hands), but also adjacent higher-level multimodal regions responded to concepts with a high relevance of a given feature type (e.g. acoustic or action features). Activity in both modality-specific and multimodal regions was modulated by task demands indicating conceptual flexibility at various levels of the conceptual processing hierarchy. As already outlined at the beginning of this article, a hierarchy of processing circuits establishes conceptual representations (Kuhnke et al., 2020; Popp et al., 2019a; Kiefer and Harpaintner, 2020). These findings thus support hybrid models of conceptual representations combining assumptions of modal embodiment theories with those of amodal theories (Kiefer and Pulvermüller, 2012; Patterson and Ralph, 2016).

Embodied cognition theories predict that conceptual memory traces in sensory-motor areas are established through the learning-based formation of cortical cell assemblies as a direct consequence of the experience with the referent. One line of evidence comes from training studies on the experience-dependent acquisition of concepts for novel objects (James and Gauthier, 2003; Kiefer et al., 2007). For instance, human participants learned concepts of novel objects (“nobjects”) under different training conditions (Kiefer et al., 2007): Participants either made an action pantomime toward a feature of the novel object, which signaled a specific object function, or pointed to it. At test, only in the pantomime group, in which a meaningful action was performed toward the object during training, was early activation in frontal motor regions and later activation in occipito-parietal visual-motor regions found during conceptual processing. This indicates that action representations essentially constitute the concept. In the pointing training group, in which the action during training was not meaningfully related to the object, this sensory-motor activity was absent, suggesting that concepts were not grounded in action. Furthermore, at the performance level, initial learning was superior in the pantomime group compared to the pointing group (See also the video about the training study in the Video 1).

The second line of evidence comes from studies investigating experience-dependent formation of conceptual representations in experts, with real objects. For instance, only professional musicians, but not musical laypersons, activate auditory association cortex when accessing conceptual knowledge about musical instruments (Hoenig et al., 2011). Together with similar expertise studies (Beilock et al., 2008; Lyons et al., 2010), these findings confirm that the grounding of concepts in the sensory-motor circuits of the brain is the result of repeated meaningful interactions with the referent. If this experience is lacking, concepts are less rich and mainly based on verbal associations (Solomon and Barsalou, 2004). In fact, we found that deaf individuals, who could not rely on the auditory input channel since early childhood, recruited language brain systems more strongly than hearing individuals in a conceptual task (Trumpp and Kiefer, 2018). This study also showed that deaf individuals compensated the loss of the auditory channel by additional recruitment of visual and motor areas.

Returning to the beech example, when confronted with the name “beech,” for instance, a layperson may be able to retrieve other words typically co-occurring with the word “beech” such as “tree” or “forest” without having a clear idea how a beech really looks like and what it is used for. In contrast, forest rangers have profound experience and knowledge about the shape of a beech and its leaves, the texture of its bark as well as the smell and the use of its wood. This notion of experience-dependent plasticity of conceptual representation supports teaching approaches like scenic learning in foreign language teaching, where vocabulary training is accompanied by meaningful gestures and movements not only for action word but for nouns as well (Macedonia and Klimesch, 2014).

Embodiment of conceptual memory for numbers

Not only concrete object concepts, but also abstract concepts such as numbers seem to be related to perception and action. Processing number concepts (e.g. knowing that 6 is greater than 4) has been shown to involve the sensory-motor systems similar to concrete object concepts in several studies. Firstly, accessing number magnitude depends on a mental number line, which resembles visuo-spatial representations (Dehaene, 1992). Behavioral number comparison experiments (e.g. deciding, which digit is larger, 6 or 2)

provide objective evidence for the existence of an analog mental number line that has a logarithmic scale similar to the mental representation of the size or intensity of sensory stimuli (Nieder, 2005). Furthermore, neuroimaging studies consistently showed that number magnitude is represented in a parietal area (intraparietal sulcus), which is also involved in processing space (Nieder, 2005). Secondly, in addition to visuo-spatial representation, numbers are rooted in the motor system, particularly in hand actions (see also Lindemann et al., 2007). Most importantly, hand actions related to finger counting habits used in childhood to learn numbers are still activated in adults when they process numbers: Intercultural studies showed that reaction times in a number comparison experiment are strongly influenced by the finger counting habits typically used in a given culture (Domahs et al., 2010). Only in German participants with unimanual finger counting habits for numbers up to five and bimanual habits for numbers greater than five were number comparisons slower when they involved numbers both below and above five, that is numbers that require one versus two hands in the German finger counting system. In Chinese participants with an unimanual symbolic finger counting system for these numbers, this effect was absent. Moreover, finger recognition in childhood predicted later arithmetic abilities (Noel, 2005) demonstrating the relevance of sensory-motor systems for coding the meaning of numbers. In support of a grounding of numbers in the motor systems, processing number concepts enhanced activity in the motor cortex in adults (Tschemtscher et al., 2012). Hence, number concepts appear to be rooted in both visuo-spatial and action-related representations. Explicitly training children in finger counting as well as in spatial analogs of number magnitude accelerates number learning and has beneficial effects on subsequent mathematical performance even in their later school or professional career (see, Fischer et al., 2011).

Embodiment of memory for abstract concepts

Besides numbers, other abstract concepts such as abstract ideas (“justice”, “love”) or scientific terms (“gravitation”, “radiation”) also do not refer to physical objects that can be directly experienced by the senses. The representation of abstract concepts in general imposes challenges for all classes of theories of conceptual representation (see also, Dove, 2016), because their content is typically difficult to define (Kiefer and Harpaintner, 2020). Furthermore, abstract concepts are more complex and ambiguous than concrete concepts, because they apply to rather heterogeneous situations (Hoffman et al., 2013; Barsalou and Wiemer-Hastings, 2005). Therefore, all theories have to deal with a high degree of conceptual flexibility. Abstract concepts are a particular challenge for embodied cognition theories, because at the first glance, it is hard to imagine how concepts without a referent, which can be perceived or acted upon, could be grounded in the sensory and motor brain systems (Dove, 2009, 2016).

For a long time, it has been argued that abstract concepts require amodal, symbolic (Mahon and Caramazza, 2009) or verbal representations (Paivio, 1986). This view dates back to the influential work by Paivio on his Dual Coding Theory (Paivio, 1986). Paivio (1986) assumed that abstract concepts are stored in a verbal-symbolic code, while concrete concepts rely on both a visual imaginary and a verbal-symbolic code.

However, in the recent years, refined embodied cognition theories have been proposed, which are able to explain the representation of abstract concepts: We (Kiefer and Harpaintner, 2020) and others have suggested that abstract concepts might not only be grounded in the perception of external events such as situations, but also in the introspection of internal mental states and in mentalizing social constellations (Barsalou and Wiemer-Hastings, 2005; Harpaintner et al., 2018; Kiefer and Barsalou, 2013; Borghi and Binkofski, 2014) or in processing affective states (Kousta et al., 2011).

In support of refined embodied cognition theories, several studies indicate that abstract concepts not only depend on the verbal system, but also on a variety of modal systems including perception, action, emotion and introspection (for reviews, see Borghi et al., 2017; Kiefer and Harpaintner, 2020). For instance, in a property listing study (Harpaintner et al., 2018), participants generated a substantial proportion of introspective, emotional and social properties, in addition to verbal associations. In terms of quantity, however, sensory and motor properties played the most crucial role in this study. The broad diversity in participants’ listings is consistent with refined embodied cognition theories by showing that the semantic content of abstract concepts includes various semantic features. These results also suggest that only one relatively small subgroup of abstract concepts is predominantly related to verbal associations.

Converging evidence in support of refined embodied cognition theories is provided by brain activation studies. Neuroimaging results revealed activity in areas related to emotions (Vigliocco et al., 2014), mental states (Wilson-Mendenhall et al., 2013) and social interactions (Wilson-Mendenhall et al., 2013), when abstract concepts were processed. Furthermore, similar to concrete concepts, subgroups of abstract concepts have been shown to activate visual and motor areas, also involved in perception and action (Harpaintner et al., 2020). Abstract physical concepts related to periodicity (e.g. “frequency”) activated postcentral and parietal brain regions, regions found to be active when performing rhythmic movements (Mason and Just, 2016).

Hence, these findings demonstrate that even fairly abstract concepts are rooted in modal systems including emotions, introspection, perception and action in line with embodied cognition theories. This sort of evidence is incompatible with Piaget’s (Inhelder and Piaget, 1958) view that scientific or mathematical concepts exclusively build upon abstract formal logical reasoning. We argue that a grounding in experiences is necessary for a rich understanding of abstract concepts, whereas knowledge is superficial, when only based on verbal instruction. We therefore propose that abstract concepts should be taught by providing learners with meaningful visualizations or movements.

Embodiment of memory for events

Past events such as incidences happening at our summer vacation are stored in episodic memory, the long-term memory system for events (Tulving, 1972). When we recall these events, we reactivate stored sensory-motor experiences collected during the initial learning episode and not only abstract-symbolic verbal knowledge (Engelkamp and Jahn, 2003; Waldhauser et al., 2016). These reactivations of acquired sensory-motor memory traces are not epiphenomenal, but are essential for memory performance (Waldhauser et al., 2016). The so-called enactment effect nicely illustrates the importance of rich sensory-motor experiences for episodic memory (Engelkamp and Jahn, 2003): Participants remembered a list of action verbs better when they performed the corresponding actions in the learning phase compared with a condition when they simply read the words. Observing others, who performed the action, also improved subsequent memory compared with reading, but was inferior to self-performed actions (Senkfor et al., 2002). Neurophysiological recordings of brain activity during memory recall revealed an activation of motor areas only for self-performed actions during learning (Senkfor et al., 2002) suggesting that action representations established during word learning were reactivated and facilitated memory retrieval.

Reactivations of stored experiences in modality-specific brain areas (i.e. areas specifically engaged in perception or action) during memory retrieval are not only observed for self-performed actions, but also for sensory information associated with the learning episode such as vision or sound (Ranganath et al., 2004; Waldhauser et al., 2016). Hence, episodic memory is based on a reinstatement of sensory and motor experiences and in this sense rooted in the sensory-motor systems (Engelkamp and Jahn, 2003). Providing the relevant sensory and motor information during learning improves subsequent memory performance compared with pure verbal learning. The results suggest that teaching strategies such as (language) learning through drama, “experiments” and outdoor activities, e.g. in science learning, are suitable to support the building of memory by providing sensory and motor information (e.g. Uysal and Yavuz, 2018). Moreover, the enactment effect indicates that vocabulary training of action verbs can be improved by the corresponding meaning-related movements.

Embodiment of reading and writing

Writing is a manual sensory-motor skill, which depends on the acquisition, storage and execution of complex motor programs (Palmis et al., 2017; Heuer, 2016). Reading, in contrast, is typically considered to be purely based on visual information (e.g. McClelland and Rumelhart, 1981). However, embodiment theories predict that reading performance might be influenced by writing techniques, because the motor programs and sensory experiences during writing (e.g. forming specific letters and words with a pen) are assumed to be implicitly re-activated during reading. As a consequence, our habitual writing techniques could affect reading performance. This issue is particularly important, because nowadays digital writing devices associated with the use of mobile phones, tablets or computers have frequently replaced writing by hand (for an overview, see Kiefer and Velay, 2016). The sensory-motor experiences during handwriting (haptic, motor, visual etc.) are quite different from those during typewriting, mouse clicking or tapping on digital devices. In particular, handwriting requires carefully reproducing the shape of each letter, whereas in typewriting no such grapho-motor component is present. Given that children in our present days may learn writing by typing on a computer or mobile phone much before they master handwriting, it is important to know how this dramatic change in writing habits in the digital age affects reading performance (Mangen and Balsvik, 2016). Consistent with embodiment theories, several training studies in preschool children and adults showed that handwriting training of new letters resulted in better letter recognition in a subsequent test than typing training (e.g. Longcamp et al., 2005). This demonstrates that handwriting, which links rich sensory-motor representations to perceptual letter shapes, improves subsequent letter reading performance compared with typewriting. Furthermore, visual recognition of letters activated motor regions of the brain, only when letters were trained by handwriting, but not when they were trained by typewriting (James and Engelhardt, 2012). This supports the assumption that sensory-motor experiences must be meaningfully related to the learning target (here: shaping a letter by writing vs. pressing a key associated with a letter) to result in stronger sensory-motor memory traces that facilitate learning (Kiefer et al., 2007).

Although some intervention studies seem to suggest a superiority of handwriting training over typing training on subsequent reading and writing performance in young children, results are mixed. Improved letter recognition after handwriting training compared to typing training was not always replicated (Kiefer et al., 2015). Unfortunately, effects at the word level are also heterogeneous: A superiority of handwriting over typing training on word writing performance (Cunningham and Stanovich, 1990; Kiefer et al., 2015) was not found in other studies (Vaughn et al., 1992; Ouellette and Tims, 2014). Mayer et al. (2020) therefore investigated the influence of the writing tool on the acquisition of literacy skills at the letter and word level with various tests in a large sample of kindergarten children ($n = 147$). Using closely matched letter learning games, children were trained with 16 letters by handwriting with a pencil on a sheet of paper, by writing with a stylus on a tablet computer, or by typing letters using a virtual keyboard on a tablet across seven weeks. Training using a stylus on a touchscreen is an interesting comparison condition for traditional handwriting, because the slippery surface of a touchscreen has lower friction than paper and thus increases difficulty of motor control. Visuo-spatial skills were also assessed, in order to test, whether the different training regimens affected cognitive domains other than written language. Children of the pencil group showed superior performance in letter recognition and improved visuo-spatial skills compared with keyboard training. Keyboard training, however, resulted in superior performance in word writing and reading compared with handwriting training with a stylus on the tablet, but not compared with the pencil group. These findings indicate that handwriting with pencil fosters acquisition of letter knowledge and improves visuo-spatial skills compared to

keyboarding. At least given the current technological state, writing with a stylus on a touchscreen seems to be the least favorable writing tool, possibly because of increased demands on motor control. Writing training with a stylus on a tablet led to inferior reading and writing performance at the word level compared with keyboarding. At the same time, the beneficial effects of hand-writing training on letter recognition and visuo-spatial skills were less pronounced compared with writing with a pencil.

Conclusion

Accumulating evidence indicates that cognition is fundamentally rooted in the modal systems of perception, action and introspection. Recent studies suggest that even the most complex and abstract thoughts are grounded in these modal systems and are not abstract-symbolic. Findings from many cognitive domains thus demonstrate that human cognition depends on appropriate sensory-motor experiences to function at the highest level. Embodied cognition theories and associated empirical evidence is therefore naturally highly relevant for many issues associated with education (O'Loughlin, 2006; Kiefer and Trumpp, 2012; Kiefer et al., 2022): Embodied cognition theories highlight the relevance of experiential interactions with our environment during learning resulting in more enduring and—perhaps most importantly—in richer knowledge. These experiences frequently include perception and action, but may also be related to introspection of emotional and other mental states.

Embodied cognition theories thus confirm and considerably expand Piaget's theory of cognitive development, which has influenced education for many decades (Benz et al., 2015). Piaget's theory emphasized the role of sensory-motor experience for children before adolescence in line with embodied cognition theories (Piaget, 1952). Reception of Piaget's theory led to changes in school curricula and promoted integration of active, self-regulated learning phases into the lessons. However, according to Piaget's stage model (Inhelder and Piaget, 1958), secondary school students as well as adults acquire knowledge based on formal cognitive operations, detached from sensory-motor experiences. Embodied cognition theories and available evidence in this field, however, contradict Piaget's notion of formal logic operations being detached from modality-specific experiences and emphasize the importance of perception, action and introspection even for most abstract adult cognition. Hence, according to the embodied cognition view, discovery learning and experiential learning activities foster knowledge acquisition also in secondary schools and in adult education.

Consider the example of learning about a beech at the beginning: According to an amodal view of cognition, it would be sufficient for the teacher to verbally describe the shape of the trunk and the leaves, the texture of its bark, the use of beech wood for carpentry etc. in a written text. A direct experience with the object is not necessary. According to embodiment theories, rich knowledge about the unfamiliar concept beech can only be acquired when the students can see, touch and act upon the object. A pure verbal description should result in impoverished, less durable knowledge. As conceptual cognition is the basis for thought, language and problem solving, knowledge embodied in perception, action and introspection is crucial for the developing mind and for achieving educational success.

Introduction

For more than two decades, the fields of Educational Data Mining (Baker and Yacef, 2009; Baker and Inventado, 2014) and Learning Analytics (Siemens and Baker, 2012; Siemens, 2013) have received growing prominence in research, policy and public practice literature. These fields have evolved from the applied disciplines of Machine Learning, Intelligent Tutoring Systems and Data Mining, which, in turn, have grown out of Applied Statistics, Education, Psychology, Cognitive Science, and Computational Linguistics. Two separate research societies formally focus on these areas: namely the International Educational Data Mining Society and the Society for Learning Analytics Research. However, the work has become so ubiquitous that it features prominently across the gamut of research societies focused on a wide range of areas under the broad heading of technology enhanced learning. Due to its expansive nature and the existence of earlier review articles recounting the history and scope, this chapter will not attempt to offer a comprehensive review of research in the areas of Learning Analytics or Educational Data Mining. Instead, the aim is to take a step back and consider some key lessons learned as well as potential steps forward.

At its core, a fundamental tenet of both Learning Analytics and Educational Data Mining is the idea that decision making regarding the administration of learning at all levels should be guided by data—both data about learners in general, and data about specific learners. In order to support design and decision making, causal models and appropriate generalizations are needed. Although these claims may come with strong caveats (Rosé et al., 2019). In particular, in embracing the value of empiricism, we must acknowledge the dangers of atheoretical empiricism (Wise and Shaffer, 2015). Theoretical frameworks are grounded in empiricism, but safeguarded through deep questioning and meaning making, which challenge us to separate spurious correlations from meaningful generalizations. Recent work on bias and fairness in Artificial Intelligence raise awareness of the harms that may arise when such consideration is glossed over (Gardner et al., 2019; Ferguson et al., 2016). With these tensions in mind—valuing empiricism while challenging total empiricism with theory grounded questioning—we embark upon this partial, but reflective, review.

The work of the field of Learning Sciences is to contribute to theories of how people learn, and then to work within those theoretical frameworks to effect positive change in the world. Computational tools, which include machine learning approaches, can serve as lenses through which researchers may make observations that contribute to theory, as machinery used to encode operationalizations of theoretical constructs, and as languages to build assessments that measure the world in terms of these operationalizations. In short, they are augmentations of human observation. They are more limited in the sense that, through the necessary discretization that takes place in applying them, the richness of signal is reduced from that in the real world. However, they are also more powerful in the sense of the speed and ubiquity of the observation that is possible. Thus, though the Learning Sciences community may include those who can fundamentally extend the abilities of computational approaches, the work of the community is in using these approaches to advance separate goals. On the other hand, that does not mean it is advisable for Learning Sciences researchers to be disinterested consumers of this technology. It would be more advantageous to strive to understand how to appropriate fully this technology as it grows and changes so that the work of the community can be accomplished more effectively.

Hot topics in recent work

In the past few years, capitalizing on its affordances, some of the most exciting work in Learning Analytics has aimed to scale up that technology in order to serve the large and diverse populations that recent trends in technology enhanced learning require.

The recent circumstances have revealed the need for such consideration, especially in times of crisis, as we have seen in the emergency move to online instruction necessitated by the pandemic. Taking a more expansive view of what can be learned about learning from data at scale—in terms of population size, temporal scope, geographic expanse, and subject matter diversity—some specific areas of focus including temporal analysis, multimodal analysis, and social network analysis have gained prominence. Bringing all these threads together, a reconsideration of the role of theories in rendering the technology safe and effective has again emerged.

Temporal analysis, also known as time-series analysis, has become an essential approach for investigating learning trajectories, styles, and strategies using process data, such as log data from digital platforms. The literature indicates that temporal analysis, combined with descriptive statistics, could enrich understanding of complex learning processes. In a recent study conducted by [Saint et al. \(2020\)](#), an online system captured computer engineering undergraduate students' interactions with learning materials, such as correctly solving assessment items and playing course videos. These interactions were categorized into self-regulated learning processes, such as setting goals and making plans. The study suggested that combining simple frequency measures and temporal analysis offered novel insights into patterns of self-regulated learning. While temporal analysis provided deep insights into learning processes, the field raised the issue of the choice of techniques affecting findings. [Matcha et al. \(2019\)](#) compared three different techniques (i.e., sequence, process, and network techniques) for identifying learning styles. As the three techniques generated different results, the authors argued that researchers and practitioners should interpret these results based on well-grounded learning theories and data analysis should also be based on such theories for generating meaningful learning strategies. Given the power of temporal analysis in expanding understanding of learning processes, researchers have devoted efforts to turn such insights into information that educators could use to monitor learning progress. Data storytelling (DS) principles have been applied to learning dashboards to support educators in interpreting findings from temporal analysis. An evaluation study with teachers demonstrated that integrating DS principles held the promise of helping teachers to interpret complex learning processes effectively ([Echeverría et al., 2018](#)). Furthermore, it has been noted that providing multiple layers of stories and engaging end users to select and combine layers to locate relevant information for feedback could support active exploration of learning progress ([Martinez-Maldonado et al., 2020](#)). Investigating strategies to engage end users to interpret results from temporal analysis is continuing to be a promising future research direction.

As learning activities are much broader than what digital platforms can currently provide, multimodal learning analytics has gained momentum with the aim of examining patterns based on discourse, gesture, and other modalities in a wide range of settings, especially collaborative learning settings. Based on the common understanding that communication and collaboration is naturally multimodal, [Cherubini et al. \(2008\)](#) collected multimodal data, including gaze movements, utterances, and gestures to build a model to detect misunderstanding during collaborative tasks. In this study, students worked in small groups to use a mapping tool to make a plan for organizing a festival on their campus. The study revealed that combining a linguistic model of utterances and eye-tracking data was effective for detecting misunderstandings. Contributing to examining collaborative learning with multimodal analytics, [Schneider et al. \(2020\)](#) captured moments when students focused on a common reference in identifying design principles for organizing warehouses in small groups. The study proposed that these moments provided nuanced information about how students negotiated ideas. In another study, researchers utilized multimodal analytics to derive deep insights about team-based, project-based learning activities in face-to-face settings ([Spikol et al., 2018](#)). It was a novel piece of work that was situated in a project-based learning setting that involved complex interactions among students and interactions between students and digital and physical materials. Collectively, these studies demonstrated that combining modes of data could uncover novel and valuable insights about collaborative learning. However, a single modality of data might be more suitable for real-time interventions ([Vrzakova et al., 2020](#)). There is need for more work in balancing trade-offs between the interpretability of complex learning processes such as collaborative learning and usability of multimodal analysis for real-time intervention.

Social network analysis has been widely used to probe collaborative learning. Addressing the gap within the theoretical framing in learning analytics research, [Kent and Cukurova \(2020\)](#) operationalized collaborative cognitive load theory ([Kirschner et al., 2018](#)) using social network analysis. They generated analytics of interactivity gains and coordination costs from students' interactions in online discussions. This study discussed the importance of visualizing these theoretical constructs for educators to support students' online collaboration. Meanwhile, studies in social network analysis have revealed that different methodological choices influenced the validity of the measurements, changed the insights obtained, and impacted the generalizability of results ([Saqr et al., 2020](#)). This implies that methodological choices should be presented in detail to ensure reproducibility and generalizability. Furthermore, intervention studies have been conducted to evaluate the potential of using social network analysis to monitor real-time collaborative learning. Through an experimental, observational repeated-measurement design, researchers found that social network analysis could be used to identify aspects related to teamwork in need of improvement, inform the design and implementation of intervention, and assess the efficacy of such intervention ([Saqr et al., 2018](#)). Research in real-time social network analysis is increasing and is worthy of study for supporting collaborative learning.

The scalability of learning analytics is receiving increasing attention as studies have shown evidence that these techniques enriched interpretation of learning in contexts and provided real-time feedback for end users. As an example, [Hutt et al. \(2019\)](#) used generic interaction features such as watching a video to model affect in math learning with around 70,000 students. The generic interaction features were used to ensure scalability and generalizability of the study findings. Students answered affect surveys after using a math learning platform. The authors explained that, in general, these generic interaction features could effectively predict affective states. Also, they suggested that some features were more closely related to affective states than others. This study implied

that interactions with platforms should be aligned with affective states so that these generic interaction features could be used for such prediction tasks. More work in scalability and critical evaluation on scaling learning analytics across contexts is needed to close the gap between gaining novel insights from learning analytics to translating these insights into concrete recommendations for practice at scale.

Focus area: analytics of unstructured natural language data

In the wake of the pandemic, we must acknowledge having been reminded of the importance of human contact and human interaction. In preparing for potential future events of a similar nature, it would benefit us to work toward more effective support for human-human interaction online. Human language is incredibly versatile and unique as a form of data in affording human interpretability, context-specificity, creative symbolization, levels of abstraction, and juxtaposition of frames of reference. Work in the area of natural language processing offers the opportunity to challenge the boundaries of what is possible to achieve within the neural revolution, the current paradigm of machine learning that drives recent innovation. Within this scope, we engage directly with the basis of what makes problems learnable: representations. We use these powerful representations to bridge to those of other forms of data, as highlighted in the previous section. Discourse Analytics is one area within the field of Learning Analytics (Buckingham-Shum et al., 2013, 2014), which focuses on natural language data as the target. It includes processing of open response questions in educational contexts, and a large proportion of research in the area focuses on assessment of writing, but it encompasses more than that, including analysis of discussions occurring in discussion forums, chat rooms, microblogs, blogs, and even wikis.

Discourse analytics in computer-supported collaborative learning

Research in the field of Computer Supported Collaborative Learning (CSCL) has produced technology for automating analysis of collaborative processes in real time (Rosé et al., 2008; Mu et al., 2012; Gweon et al., 2013; Fu et al., 2016) and using this analysis to trigger in process support that increased the effectiveness of collaboration and student learning (Kumar et al., 2011; Dyke et al., 2012; Adamson et al., 2014). Many frameworks have been developed for automated analysis of student discussion, as it has repeatedly been shown to be valuable for assessing student learning (McLaren et al., 2007; Dascalu et al., 2015; Rosé et al., 2008; McLaren et al., 2007; Ai et al., 2010; Gweon et al., 2013; Fiacco and Rosé, 2018), supporting group learning (Kumar et al., 2007), and enabling effective group assignments (Wen et al., 2016). Some work has explicitly addressed the issue of whether these frameworks generalize across domains (Mu et al., 2012; Fiacco and Rosé, 2018; Fiacco et al., 2021), which is critical to enabling educators in a variety of fields to leverage these tools. Consensus building and knowledge integration behaviors such as transactive conversational contributions have been a major focus of work in social analytics. Many of these conversational behaviors involve articulation of mental models and drawing connections between one's thinking and that of others. Successful collaborative learning is broadly believed to be fostered by discourse patterns characterized by the articulation of reasoning and idea co-construction (Chan, 2013; Chinn and Clark, 2013; van Aalst, 2009), which have theoretical connections with cognitive conflict and learning (de Lisi and Golbeck, 1999). On the other hand, building a shared understanding need not imply coming to an agreement, or avoiding disagreement (Holtz et al., 2018). Though much work takes a coding and counting approach, other work challenges whether this is enough, and proposes techniques that consider co-occurring codes within time windows to gain a richer sense of process (Csanadi et al., 2018). More recent work focuses on newer theoretical frameworks for evaluating collaborative learning processes, such as Social Regulation and Socially Shared Regulation of Learning (Su et al., 2018).

Discourse analytics in automated analysis of student writing

Automatic writing evaluation and feedback technologies have the potential to facilitate students' ability to learn to produce high-quality essays (McGarrell and Verbeem, 2007; Roscoe et al., 2013), thus developing writing skills that are important for their future success (Burstein et al., 2017; Cotos, 2011). While this aspect of learning analytics applied to human language is not formally focused on human-human communication processes, the skill of writing is essential for students to gain in order to be effective communicators in their adult professional lives. Writing is a key skill that has suffered alongside other areas of instruction in the pandemic (Kuhfeld et al., 2020; Engzell et al., 2021; Hamilton and Ercikan, 2022).

The field has developed Automated Writing Evaluation (AWE) and feedback technologies to facilitate students in writing well-organized essays (i.e., one idea flows logically to the next). While these technologies (e.g., Coh-Metrix (McNamara et al., 2010), Writing Pal (Roscoe and McNamara, 2013), Revision Assistant (West-Smith et al., 2018), and AcaWriter (Knight et al., 2020)) offer significant benefits for providing feedback for idea organization and flow, typically, they rely on local features, such as discourse markers and other syntactic indicators of attempts to signal rhetorical structure.

Writing feedback that is both adapted to an individual student's text and to the expectations of a given assessment may lead both to greater improvements in writing quality and a perception of more helpful feedback (Burstein et al., 2001). Even in recent published work, for example, it is reported that after using the AWE tool, MI Write, both students and teachers commented that the tool was able to provide general feedback but could not point out specific weaknesses of the, often ill-structured, essays (Palermo and Wilson, 2020). The need for offering advice on improvement of structure and flow is partially addressed in work grounded in

sequences of rhetorical moves and steps for the specific genre of scientific writing, where missing moves or steps can be suggested (Cotos, 2011; Fiocco et al., 2019). However, this is a schema-based approach grounded in a specific genre of writing and does not enable a generalizable form of evaluation of rhetorical structure.

Currently, automatic writing evaluation is effective at measuring the qualities already exhibited within an essay, however it remains an open challenge to be able to highlight missing qualities and provide insights on content to add. Even experienced human raters have considerable difficulty pinpointing specific and concrete weaknesses in free-form essays (Roscoe et al., 2018). The features targeted by current writing tutors are highly indicative of writing quality, serving as organizational features that relate to an abstract notion of “cohesion,” which has been observed to decrease with writing quality (Uccelli et al., 2013; Woods et al., 2017). However, identifying these features is not the same thing as analyzing the organization or architecture of ideas within an essay, for example, identifying what is the core idea and how the other parts serve to offer background, justification, or critiques.

Meanwhile, researchers have leveraged various discourse parsing techniques to generate automatic structural writing feedback that takes steps toward this more architectural notion. For instance, Cotos (2011) argued that automatic identification of steps and moves as discourse elements was essential for providing feedback for highly structured and generally well-written essays like multi-section academic papers. In another study, Burstein et al. (2001) showed evidence that a framework referred to as Rhetorical Structure Theory (RST) (Mann and Thompson, 1988) could be used to detect discourse components such as thesis statement and conclusion, even with a relatively small corpus of human-annotated essays. They suggested that AWE systems should strive for providing specific structural writing feedback for free-form essays.

To add to this discussion, the author team of this article conducted a semi-structured interview study with teachers in order to build a vision toward next steps for the field, specifically in design for feedback on structure and flow of writing. In this interview study, the interviewer played the role of a student who wrote an essay, and the teachers walked the interviewer through the feedback that they would give to help the student improve the organization of the essay. From this we learned from teachers’ expressed perspectives that common organizational concerns in essays included: disconnected introduction (i.e., sentences in the introduction or first paragraph are not logically connected to present a clear thesis statement), body sections (i.e., paragraphs in the body do not connect to the main idea, and do not flow naturally from each to the next), and conclusion (i.e., final paragraph does not connect back to the ideas presented in the essay). These organizational concerns have not been fully addressed in the field of Automated Writing Evaluation (Wilson et al., 2017).

In addition, the process of giving feedback to address those organizational issues in the classroom usually involves helping students to reflect on the connections between sentences and paragraphs. In particular, teachers first identified weak spots, and then guided students to address missing or unproductive connections by iteratively reflecting on connections at the word, sentence, and paragraph level. For instance, after reading a student’s essay about positive values of sports, the teacher pointed out that “his major weakness is in his introduction, for the reader, by looking only at the introduction is clueless about the writer’s thesis about sports.” Specifically, the teacher first directed the student (the interviewer) to take a global perspective to summarize the thesis of the essay and then moved to local analysis of three sentences in the introduction, “what additional words and sentences need to be there (between sentences) so that anyone who picks this up would understand how much you love sports so that then that flows into there are a lot of positive values to playing sports (emphasizing the thesis of the essay).” Afterward, the teacher led the student to evaluate word choices in one of the three sentences, “I went back and glanced at your introduction again, and one thing that really threw me in your introduction was, when you were working on a hook, the word however.”

The iterative process in reflecting on idea organization across different levels indicates that we might need to present both a local and global view of writing structure for students to take meaningful actions in revision. One way of looking at the process we heard teachers discuss is that they first identify islands of cohesion within student writing and then seek to help students integrate those islands into a better structured whole. This might be accomplished through an automated process of segmentation, where the writing is deemed well-structured within segments, but not across segments.

To prompt continued work, we hypothesize that RST, a framework for connecting texts at multiple levels (e.g., sentences and paragraphs), might provide a standard for segmentation, which might then be automated, and used to provide automated feedback to improve structure and flow. RST is a popular approach to analysis of the structure of writing that leverages principles of the dependency-based hierarchical nature of text and is common across genres (Mann and Thompson, 1988). In RST, relations between segments of text called Elementary Discourse Units (EDUs) are represented as a tree, an example of which can be seen in Fig. 1. Unfortunately, though RST is one of the most popular theoretical foundations for analysis of hierarchical discourse structure, and though automated analysis of RST is a benchmark task in the field of Language Technologies, availability of labeled data for training automated models remains limited (Jiang et al., 2019). In particular, datasets for RST are time consuming to annotate and require a high degree of expertise to achieve reliability and this is especially true for student writing which often has unusual, or is lacking, structure (Jiang et al., 2019). Available public corpora of data with RST annotations are small relative to the magnitude of annotated data available for training syntactic parsers. Considering both the dearth of annotated data and the challenges of decision making for discourse relations based on local context, it is not surprising that RST parsing has remained a challenging task that has had only incremental improvements even since the deep learning revolution (Li et al., 2014, 2016; Ji and Eisenstein, 2014; Braud et al., 2017; Yu et al., 2018; Mabona et al., 2019). Improvement of automated RST parsing is a direction for future research in this important area. Future work in this area of computational linguistics would potentially have a transformative effect on this area of research.

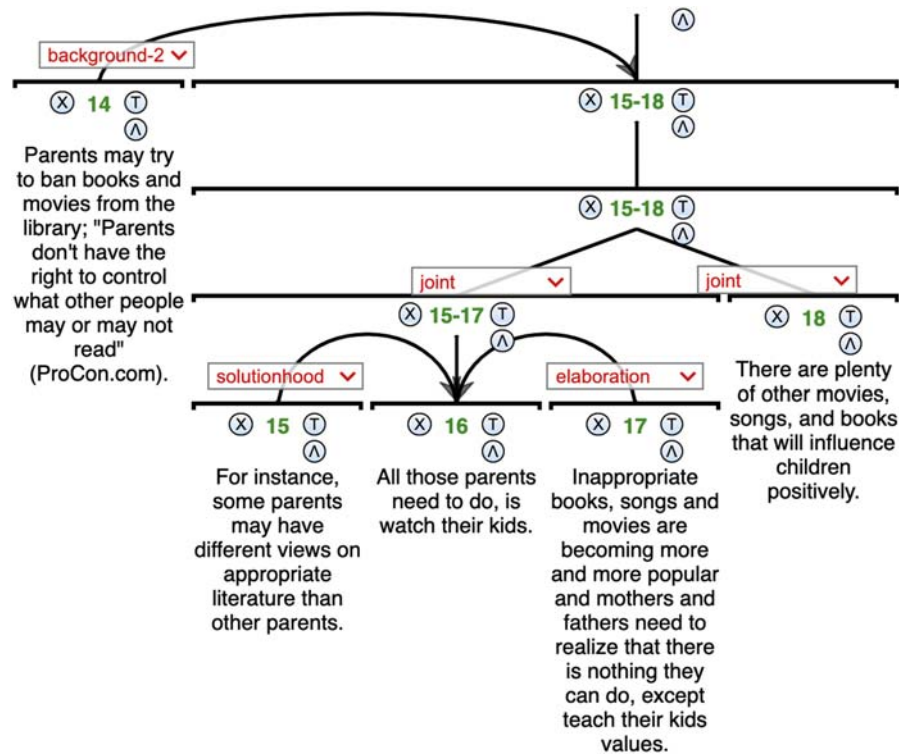

Fig. 1 Example RST tree of a fragment of student writing.

Conclusions and vision for the field

As we reflect on the field of Learning Analytics in light of our experiences in the pandemic, we have considered the connection between data and the human experience at a grand scale. We first considered emerging areas in the field that show promise for achievement of operation at scale. Recognizing where these technologies and this learning are contextualized within human experience, and in particular, human-human relationships and interconnectivity, we considered in depth the area of learning analytics applied to human language. Expanding out from this more specific focus, we are faced with the reality that, even in light of great advances in the field, there was a breakdown in bridging from research into practice that might have buffered some of the learning loss and disruption experienced in the pandemic.

A recent public engagement workshop bringing together the worlds of research, policy, and practice surfaced the need to consider more deeply the social and political context of the technology, taking care to provide scrutability, explainability, and mitigation of bias and unfairness alongside needed teacher training and support (Rosé, 2021). Some notable work provides a foundation on which to expand in the coming years. For example, though the problems are far from solved, a limited amount of research has carefully considered ethical issues related to bias and fairness specifically in the area of learning analytics (Gardner et al., 2019; Ferguson et al., 2016). The transition of research into practice is explored as a formal research endeavor on its own in work illuminating the issues surrounding adoption (Dawson et al., 2018; Macfadyen et al., 2014; Macfadyen and Dawson, 2012).

Though the focus of the field at large is on isolated studies and investigation of data sets and models, some notable work focuses specifically on the role of the teacher (Van Leeuwen, 2019; Van Leeuwen et al., 2019) or delves deeply into classroom culture, values, and orchestration (Chen and Zhu, 2019; Martinez-Maldonado, 2019; Tissenbaum and Slotta, 2019), and eventually views learning processes from the perspective of improvement of school systems (Krumm et al., 2018) especially regarding early detection and mitigation (Waddington et al., 2016). This bridging from the data sets and models we know how to work with, to the more unwieldy, larger, and largely untamed world of teaching in practice, is what we need going forward, especially as learning processes touch those aspects of learning most critical to human existence, learning, and sustainability.

Introduction

Consider the following examples. Beverly, while starting her car, raises her wrist to her mouth and requests directions to her next appointment. Her request to the digital assistant is not understood at first, but it is after her second attempt. Since she first began using her smart watch, she has noticed a decrease in the times she must repeat herself. The watch is learning her voice and speech patterns. A few weeks later, she raises her wrist to find that her device is already offering to navigate to that location. It has recognized that every Thursday at 4:00 p.m. she travels to the same place. Beverly accepts the directions and heads down the road.

Across town, Jamal (a college sophomore) is figuring out which textbooks to purchase for his coming semester. Opening Amazon, he sees various college-related supplies being recommended; most of which are already monogrammed with his school's mascot. He selects his first textbook and notices that the site is suggesting another book commonly bought with the one he has selected. Checking his list again, he sees that the recommended book is also required. Both go into his shopping cart. After closing the browser, he sees a notification from his favorite social media platform. A "friend" has uploaded a somewhat embarrassing photo of them from the prior evening. The app has recognized Jamal's face, and is asking if he would like to be tagged in the photo. He declines (while also making a mental note to talk with his friend about posting photos online without permission).

These examples all fall under the umbrella of Artificial Intelligence (AI), which increasingly appears in the news because of the breadth of its reach. Part of this breadth comes from the generality of its definition. John McCarthy—who first coined the term in 1955—defined artificial intelligence as, "the science and engineering of making intelligent machines, especially intelligent computer programs" (Stanford University, n.d.). The purpose of AI is to model human thinking, and eventually surpass it. Because it is such a broad term, AI has found application in nearly all areas that make use of technology and data. The specific area within AI where the opening examples fall is called machine learning (ML).

ML has become a popular buzzword in recent years and is often incorrectly used interchangeably with AI. Rather, ML refers to the process by which a computer attempts to find regularities or patterns from a set of data—like speech patterns, purchasing habits, and facial features described in the examples above. Accurate recognition of patterns requires the algorithm to be exposed to large sets of examples. In this way, the algorithm "learns" to identify patterns that it can then recognize in novel data. Even then, the algorithm may, if provided the capacity to, improve itself by learning from feedback loops that inform it of cases which were mistakenly identified.

In the opening illustration, with Beverly's smart watch not recognizing her voice, the ML algorithm embedded within the device might take an initial sample of her speech patterns, but whenever Beverly must repeat herself, the algorithm identifies that as a mistaken interpretation and improves itself for future interactions. The watch may be artificially intelligent, but it is machine learning that allows the watch to improve over time. Another example of ML in use today is how Uber uses ML algorithms to predict how long it will take rides (or meals) to arrive, set pricing, and even determine where best to wait to give a driver the best odds of finding you for pick-up (GeekWire, 2016). These algorithms are specific to their purpose and likely trained using data they mined from their own apps. Finally, it is the ML technology behind driverless cars that can quickly adjust to diverse conditions while driving. The continual self-improvement of the algorithm, however, is what makes it truly "intelligent." ML is not the same as AI, but ML does provide AI with the ability to learn and improve.

What is machine learning?

Think of Pavlov's dogs. When he would ring a bell, they started to salivate. Pavlov taught them this pattern: every time the bell rings, food is on the way. The dogs soon learned the pattern and eventually began to respond to the bell *before* the food appeared. To cognitive psychologists, human brains are also natural pattern matchers. Since birth, we are constantly trying to find patterns in what we perceive, then associate new patterns with existing patterns in our memory. This pattern-matching process happens automatically. Through our everyday experiences, our brains are constantly collecting new patterns and adding them to memory. These patterns then influence the inferences and decisions we make in the future.

Inspired by an understanding of how the human brain works, researchers in the field of ML draw on connections to psychology, neuroscience, and the learning sciences. These connections are evident in the use of shared or similar terminology (e.g. reinforcement learning). Tom [Mitchell \(1997\)](#) wrote a widely quoted definition of ML: "A computer program is said to learn from experience E with respect to some task T and some performance measure P , if its performance on T , as measured by P , improves with experience E " (p. 2). Machine learning focuses on developing algorithms that allow machines to improve their performance on a certain task over time through accumulating experiences. Going back to Beverly, her watch implements an ML algorithm to understand her voiced instructions. Although the initial performance is not fully satisfying (i.e. she had to repeat herself several times), the watch becomes better over time as it experiences more instances of Beverly's voice. Modern companies that build these voice-recognition systems often pre-train the algorithm with massive amounts of voice recordings covering a wide range of accents, volumes, and acoustic environments prior to selling them to the customers. The initial accuracy of the watch's voice recognition should be acceptable, but it is further improved by specifically learning its owner's voice.

Approaches to training

Although all ML approaches share the goal of automatically improving performance on a task based on accumulated experiences, they differ largely on the target task, the nature and availability of training data, and the measure of performance. Given the complexity and variability of typical problems addressed with ML, there is no one-size-fits-all approach to training. Although not a comprehensive list, the three largest categories are: supervised learning, unsupervised learning, and reinforcement learning.

Supervised learning

In supervised learning, the ML algorithms are trained using large collections of examples that are *labeled* with the correct "answer." Similar to how one studies for a test by completing endless practice problems, the algorithm "learns" how properly to identify or classify a given input by processing large, labeled datasets until it can do so with an elevated level of confidence—the larger the training set with rich and diverse examples, the more accurate the algorithm.

A simple example of supervised learning involves training an algorithm to differentiate between images of cats and dogs. The training dataset consists of a huge selection of different images showing either a cat or dog, along with its correct label. The algorithm "studies" these examples by identifying patterns within the pixels. Then, when provided with a novel (unlabeled) image, the algorithm will look for similar patterns and provide an answer—although "best guess" might be more appropriate—and a level of confidence. Now, what happens when the algorithm, trained on nothing but cats and dogs, is given an image of a rabbit? There are certainly similarities that could be drawn between rabbits, cats, and dogs, but the algorithm can only choose between the latter two animals. It will have to choose whichever category the rabbit image most closely resembles, but the confidence of the result will likely be low.

The training data are critical to a successful supervised learning approach, but reliance on the training data is also a limitation. If high-quality training datasets (i.e. containing accurate human coders' labels with unbiased and diverse training examples) are not available, it can take hundreds of hours for humans to collect and label a new training set. Moreover, if humans are doing the labeling, they must be very careful as each error will influence a dataset's quality and the overall performance of any ensuing predictive model.

Supervised learning primarily deals with problems of prediction and forecasting. Supervised learning algorithms look at existing data to make an inference about new instances or predict the outcome of a yet-to-be-seen example. And while identifying the species of pet photos on the Internet may be fun, supervised learning can be applied to data beyond images, such as using numerical data for predicting and forecasting. For example, stock prices or real estate trends, due to the potential financial gains and the ample amounts of historical data, are popular real-world examples of supervised learning. The prediction of a single house price, for instance, might use data that include several properties of individual houses in the dataset, called features. Each house might include features describing earlier sales prices, the neighborhood, square footage, number of bedrooms, and so forth. Another algorithm may be trained on patterns leading up to major shifts in the market to predict major trends in the future. Costly errors can be made when an algorithm, meant to predict stock prices, is trained on data that neglect the potential of dramatic swings in the market due to unique events (e.g. a natural disaster or war). Thus, supervised learning algorithms can have powerful predictive and discriminatory capabilities—provided the availability of enough quality training data that is also sufficiently representative of the targeted population.

Unsupervised learning

When well-labeled data is unavailable and the task of creating a labeled dataset is neither physically nor financially feasible, or when one is without preconceived categories (or unsure what to even look for), unsupervised learning may be the ideal approach. The unsupervised approach allows the algorithm to detect patterns that may be too complex for a human to recognize. The algorithm reads the unlabeled data and discovers hidden patterns within.

For instance, the construction of a commercial airliner involves millions of mechanical parts. Each part of the aircraft will have a degree of error in length, weight, or performance due to simple variation in quality control—all pieces meeting a minimum standard, but not perfect. Even though all parts individually may work without perceivable error, in a complex machine like an aircraft, the accumulated error may be catastrophic. Traditionally, technicians must manually conduct multiple systemic evaluations of the plane, which cost tremendous amounts of time and money. Using an unsupervised approach, such as Anomaly Detection, and data regarding the quality of each part, an algorithm can holistically assess the amount of accumulated error and determine to what extent the accumulated errors affect the quality of the plane's airworthiness before the plane even leaves the warehouse.

Reinforcement learning

Both supervised and unsupervised learning are powerful approaches, but sometimes real-world problems that are natural to humans can be too complex or dynamic for machines to label or model (e.g. driving a car on a highway). Compared to supervised learning, where the answers are provided upfront, reinforcement learning tackles a task with parameters for successful completion. One might draw a simplistic analogy comparing supervised learning to rote memorization and reinforcement learning to discovery learning. The algorithm works by making random attempts, each of which is provided immediate feedback, until it can successfully complete the task.

Self-driving cars are a well-known example of reinforcement learning. When training an algorithm to drive a car, one central task is to determine the optimal combination and sequence of gas pedal, brake, and angle of the steering wheel. Instead of labeling the behaviors of 1000 different drivers, reinforcement learning can happen in a *simulated* environment with a wide variety of driving situations.

The driving algorithm is given a straightforward goal: drive from point A to point B without accident and before time runs out. Any behaviors that progress toward meeting the goal are rewarded while the rest are penalized. The algorithm starts with random actions and, for a while, might not even move forward. However, after thousands of random trials, the algorithm begins to use the gas pedal to move forward (not backwards) because moving forward closes the gap between point A and point B, but it may not have learned yet how to use the steering wheel to turn. After running off the road, hitting stationary objects, making U-turns, and another million failed trials, the algorithm finally begins to guide the car to its destination. The cost of reinforcement learning is computational resources and time in simulated environments, which is relatively inexpensive and more efficient compared to crashing cars on a real road or collecting data on even 100 real drivers.

Supervised learning, unsupervised learning, and reinforcement learning are currently the most well-known approaches in ML. Other more complex approaches derive from these basic approaches. For example, semi-supervised learning and self-supervised learning combine both supervised and unsupervised learning techniques, such as using the results from unsupervised learning to inform labeling in supervised learning datasets. Additional ML approaches (e.g. ensemble learning, active learning, transfer learning) strive strategically to improve the performance of the basic approaches. These techniques do not have to be supervised, unsupervised or reinforcement learning, but they do employ strategies to improve the performance of any single model. For instance, ensemble learning combines multiple classifiers and then outputs more robust results compared to simpler approaches. Active learning can involve a human coder to resolve uncertain cases. And transfer learning, in some instances, can use pre-tuned model parameters to shorten the training time or deal with problems with fewer training examples needed.

In summary, ML is an applied field and different approaches are inspired by diverse practical problems across various disciplines. Therefore, these approaches do not necessarily all share the same theoretical foundation and historical root. Each approach to ML has developed a multitude of different algorithms for different purposes. This diversity began during the mid-20th Century and continues to evolve today.

A brief history of machine learning

As early as 1947, the British mathematician Alan Turing envisioned a machine that could, based on an initial set of instructions, modify its own operating instructions over time. The new instructions created by the machine were the result of responses to recently added information. He likened the process to students who have learned basic information from their teachers and went on to develop new knowledge on their own.

In such a case one would have to admit that the progress of the machine had not been foreseen when its original instructions were put in. It would be like a pupil who had learnt much from his master but had added much more by his own work.

Turing (1995, p. 13).

Turing's idea was too theoretical and abstract to implement in 1947, but today's development of ML is largely inspired by his vision. With modern technology, Turing's ideas have come to fruition.

One of the earliest practical examples of learning machines is often attributed to Arthur Samuel. In the 1950s, Samuel developed a computer program that could learn to play the game Checkers, a strategic board game where two players make diagonal moves and capture pieces by jumping over the opponent. Samuel's program evaluated each position by looking ahead at all the possible moves to determine the best next move. Later, he developed a simple learning method (i.e. rote learning) where, through repetitive self-play, the program memorized optimal moves given a set of conditions observed over thousands of games. Although the algorithms he used were relatively slow and limited by the computer memory at that time, the program was able to improve its performance continuously and reached the level of "better-than-average novice."

Around the same time, researchers came up with the idea for artificial neural networks (ANN) that imitate human neurons to deal with complex computing often involved in machine learning. This idea was initially discussed in the early days of machine learning (e.g. Perceptron invented by Frank Rosenblatt at Cornell Aeronautical Laboratory in 1957). In the 1970s and 1980s, classic structures of ANN were invented (e.g. Convolutional Neural Networks for image recognition and Long Short-Term Memory Recurrent Neural Networks for natural language processing). However, these efforts did not make a substantial impact outside of research labs due to the lack of computational power and limited data at the time. ANN has regained attention in recent years in the form of deep learning (i.e. multi-layered neural networks). Modern deep learning applications range from classic speech recognition and image recognition to complicated music composition, bioinformatics, drug discovery, and so on. Many applications reach the level of "experienced amateur" and some even surpass human performance. To illustrate, from 2015 to 2017, AlphaGo—a neural-network-based AI system—defeated every world champion in a strategic board game called Go (like chess). Originating in ancient China, Go is a vastly more complicated game with 361 potential opening moves compared to Checkers (four moves) or Chess (twenty moves). Brute-force assessment of every possible next move in Go, as is done in simpler algorithms used for Checkers and Chess, is beyond the computational power of any computer in existence. However, with the successful implementation of ML algorithms (e.g. Monte Carlo tree search and deep neural network), AlphaGo can play against itself just as Arthur Samuel envisioned, evolving over time in search of the optimal strategy.

Besides rote learning and artificial neural networks, ML has been influenced by many different disciplines and the field of ML has branched out to multiple lines of research through its history. For example, Email systems now routinely have spam filters to block junk emails. These filters are usually powered by algorithms like Naïve Bayes classifiers, based on Bayesian probabilistic inferences, invented in the 1970s. Later, around the 1990s, models like Support-vector machines (SVM; Cortes and Vapnik, 1995) were introduced to the ML field. They can be used for both regression and classification tasks and are typically used for classification purposes. SVMs provide an alternative, non-probabilistic method for classification compared to Naïve Bayes. Inspired by evolutionary theory, genetic algorithms were also invented around the same time as SVMs (Holland, 1992). Genetic algorithms were once widely used to solve complex and dynamic problems like scheduling optimization for flights and trains and later informed the development of reinforcement learning. The theoretical foundations and data structure of different algorithms may vary, but they all share a similar goal—identifying an optimal solution based on existing and incoming new data. Now, having laid a foundation about ML in general, we next describe how ML can be used in education.

Machine learning in education

At its core, the purpose of ML is to solve problems and offer insight into issues too complex for human analysis, or to automate routines too costly for human labor. Successful implementation of ML algorithms reduces the reliance on human effort by automating complicated or tedious tasks. In education, there are many such tasks that could benefit from ML. For instance, a report published by the Organization for Economic Cooperation and Development (OECD) in 2015 found that teachers spend, on average, about half as much time teaching as they do on non-teaching tasks including lesson planning, grading, administrative work, and collaboration with other teachers. Moreover, teachers struggle to provide equal attention to all students in addition to preparing high quality instructional activities to classrooms of 30+ students. Struggling students are often left alone to grapple with difficult subjects before the class moves on to the next topic. Such unaddressed gaps in learning may plague students for years.

The opportunities for ML to benefit the field of education are bountiful; however, change in education is often slow. Developing and implementing ML-powered systems requires significant financial investment, expertise in both education and machine learning techniques, and extra caution when dealing with vulnerable populations. For these reasons, intelligent machine aids are only slowly making their way into schools worldwide. We now describe some current ML applications that are helping both teachers and students.

Instructor aids

Teachers stand to benefit greatly from ML systems, such as in time saved from completing routine tasks that are easily automated. Such ML-powered systems can be employed to save teachers' time by grading homework assignments and exams that are in essay format. For example, the Educational Testing Service has been using an ML-based system called *c-rater* for years to score participants' essays (Sukkarieh and Blackmore, 2009).

Tools to enable facial recognition have already been shown to be helpful in simple daily tasks like taking attendance (e.g. [Okok-pujie et al., 2017](#); [Sanli and Ilgen, 2018](#)). Although checking which student is present may take between two to 10 min, depending on the class size, even just 2 min can add up to a total of 6 h across a 180-day school year. These systems, which have been tested in limited classrooms already, record the classroom at certain times throughout the day. Student faces are captured, and the facial recognition software identifies the student and marks them as present.

Attendance may seem trivial, but facial recognition algorithms can also help with the arduous task of noticing students' subtle behaviors during class. ML systems have demonstrated the ability to track facial expressions that can indicate students' engagement. Systems like these can notify teachers when students are not engaged, which in turn could prompt the teacher to change up a lesson, call for a break, or help a struggling student. For example, [Sümer et al. \(2021\)](#) used ML to analyze the audiovisual recordings from a classroom of students over a period of one and half months. They trained their engagement classifier models using two features of engagement (attention and affect). The results were promising. That is, their engagement classifier achieved an acceptable level of accuracy, which is notable because this study was the first in this area (i.e. multimodal engagement analysis in a physical classroom) and because of the relatively small amount of student-specific data used. Results from this type of research can help teachers identify whether their students are engaged or not so they can modify their teaching (e.g. slow down and elaborate, ask a thought-provoking question), as needed. Granted, facial recognition in classrooms raises issues of privacy and potential abuse. We address those concerns later.

Identifying real-time indicators of engagement is one benefit of ML, but long-term data collection can yield even more valuable insights. For example, researchers have used multiple ML algorithms to predict high-school students' risk of dropping-out based on records of coursework, attendance, and performance ([Coleman et al., 2019](#)). By recognizing patterns that lead to dropping out of courses, teachers can improve retention rates by offering interventions before the student has even seriously considered quitting, such as suggesting a student come for extra help after school prior to an important test. Moreover, ML has been used to model complicated socio-cognitive processes such as knowledge sharing and negotiation in computed-supported collaborative problem-solving contexts ([Stewart et al., 2019](#)). In general, receiving real-time data—especially that which has been accumulated over time—can provide recommendations so that teachers are able to make more informed decisions on subsequent learning activities. But ML can also benefit students directly.

Student aids

In addition to supporting teachers, ML has incredible potential for enhancing students' learning experiences. One early vision for implementing ML was to develop intelligent tutoring systems which were meant to emulate the role of a human teacher and respond to students thoughtfully as an expert tutor ([Self, 1990](#); [Shute and Zapata-Rivera, 2010](#)). In this case, ML can be used to (a) identify students' learning processes and behaviors, (b) diagnostically assess their weaknesses and strengths, and (c) provide individualized cognitive and affective supports as needed. As part of interacting within such digital learning environments, students demonstrate observable behaviors relative to targeted knowledge and skills. These behaviors could then be collected as information traces and used to train ML models, for example, identifying behavioral patterns that are successful and those that are not for various outcome measures. The models can then infer students' evolving knowledge and skill levels based on an accumulation of observed behaviors. Using these inferences, the intelligent learning environment can recommend the most appropriate learning supports or subsequent content to optimize students' learning experience. Diagnostic information and intervention recommendations can also be shared with the teacher.

Recently, the National Science Foundation granted \$20 M to an AI-institution project led by the University of Colorado, Boulder ([Strain, 2020](#)). This five-year project is targeted at middle- and high-school students and aims to improve teamwork. In the classroom envisioned by the project, ML algorithms will be used to recognize who is speaking, what is being said, and then react in real-time (e.g. provide feedback) as needed. The data collected over time will be used to create individual models of each student that can be used for formative and summative assessments. ML and similar techniques comprise the building blocks of such complex AI-based classrooms.

The costs of designing, developing, and testing intelligent systems are high, thus making them cost-prohibitive for most schools. However, many of the functions of such systems can be emulated, with the help of ML, by more familiar environments, like educational games. For instance, *Physics Playground* ([Shute et al., 2019](#)) is an educational game that incorporates stealth assessment ([Shute, 2011](#)) to estimate students' conceptual physics understanding in real-time. Stealth assessment is embedded into the game code to continually track a player's progress and support learning during gameplay using an automated statistical scoring and accumulation approach (Bayesian inference networks). Moreover, the game includes a quit-prediction model. This model can predict if a student is frustrated and is likely to quit playing. The game then can use this information (i.e. the probability of quitting for each student at any given time) to provide appropriate supports (e.g. affective supports such as motivational messages) to encourage persistence in solving game levels. The quit-prediction model uses 37 variables, also known as features, to determine the probability of a student quitting. These features were extracted from student-generated log files through an iterative ML process called feature engineering ([Shute et al., 2020](#); [Slater et al., 2017a,b](#)).

Thus far, we have looked at how a machine can assess and support student learning, both of which are dependent on ML approaches that focus on pattern recognition. Reinforcement learning provides another benefit that goes beyond monitoring and reporting on students' knowledge and skill levels. That is, reinforcement learning algorithms can provide individualized content and experiences that surpass what a single teacher could achieve. The ITSs mentioned earlier can reach a new level of sophistication

when paired with reinforcement learning. That is, earlier ITSs were dependent on rule-based, manually coded, and generalized responses to student interactions. The manual approach is limited by how many rules the designer can think of and integrate into the system. Using reinforcement learning, the ITS can adapt to learners' behaviors and select the optimum next step for learners based on their prior performance (Chi et al., 2011). Every student receives a unique learning experience, based on the insights gathered from the ML-based systems.

Taking ML's ability to generate tailored content in another direction via reinforcement learning to train and build simulated environments, individual students may interact with these environments to experiment and learn. What could only be explained with diagrams and hypotheticals can now be demonstrated in real time (or in accelerated time for slow-moving processes) as the student observes. Economic markets can be generated that mimic modern-day markets (e.g. Zheng et al., 2020). Students can adjust parameters to see how simple changes can have massive impacts. Tiny creatures can be modeled, created by students, and left to live out the perils of natural selection as students observe how they survive (or not) over long periods of time. Not only can students observe these complicated systems that have such powerful influences on our lives, but they can also create their own systems and see how they respond to different inputs. This is putting the world in students' hands and letting discovery learning take place on a whole new scale.

What does the future hold for ML in education? We believe that the influence of ML will continue to grow in educational systems around the world. Following are some ideas and examples of what we expect to see happen with ML and education in the future.

Future of ML in education

Although modern programming tools and programming libraries already make the workflow of structuring ML projects easier than before (Slater et al., 2017a,b), ML is far from accessible to the layperson. We do expect to see that, in the future, ML will become a fairly ubiquitous influence in the educational world by making insights and answers readily available to all stakeholders. For instance, educators will be able to actively use ML tools to support instructional decisions and students can use ML to diagnose their own performance without going through hundreds of hours of training only to get a single score. This accessible ML future first relies on the advancement of technology (e.g. increases in computational power). That is, although the main theoretical foundations of ML were established in the last century, applications in this field were largely restricted by the costs and limits of technology. Recent advances in computing—like quantum computing, Optical Neural Networks, and distributed computing—continue to increase computing performance and lower cost. Before long, computing resources required for more advanced ML applications, rather than being a luxury of well-funded computing labs, will be within the budgets of local school systems—making the benefits of ML more prevalent in education.

In addition to rising power and decreasing costs, this envisioned future depends on raising the bar for “basic” computer literacy. Just as the ability to read was once a luxury of the upper class, and not long ago creating content on the Internet was limited to only the technically savvy, the minimum threshold for what is considered “basic knowledge” of statistics, computer science, and engineering practices (e.g. simulation and modeling) must be raised. A transformation in society's computing literacy will take time, but we are optimistic. Again, just 30 years ago, when the Internet was young, creating a simple website required advanced programming skills. But today, anyone can create sophisticated and beautiful websites without any programming knowledge. As ML technology continues to increase in availability and become more prevalent in our everyday lives, we fully expect ML to become a basic programming skill and, one day, be a part of our children's core science curricula.

As more and more educational activities happen online, the data available to ML tools used in education will grow exponentially. The increase of data volume is predictable, and we expect the future will include the fusion of dynamic and diverse data being used for ML in education. ML will not have to focus on one model or source of data. Instead, data will come from many sources and channels. Students' academic performances (numerical data), facial expressions (visual data), classroom discourse with peers and instructors (verbal data), and engagement levels (physiological data) can all be merged to provide a holistic and more valid view of students' performance and understanding. We will be able automatically to identify that a student's difficulty in an English class is not because of language ability but due to test anxiety based on affect detection and other physiological data. In addition, data fusion can synthesize the conclusions from multiple sites (e.g. different school districts), which prevent the sharing of individual levels of identifiable digital traces. Ultimately, we can build up a comprehensive and multi-faceted data warehouse to benchmark educational ML performances and inform research and practices.

In the more distant future, we may see analytical systems, powered by ML, help individuals self-actualize by identifying dispositions and paths needed to achieve short- and long-term goals. Such ML-based systems would make the learning process more efficient, self-directed, individualized, and life-long. Through advanced personalized-learning environments, students could pursue their own interests instead of being constrained by one-size-fits-all curricula. Apart from individual support, ML-powered systems could be employed at the group level, for data-driven decision-making purposes. For instance, governments can use school, district, city, and state data to create policies and practices that can dramatically improve education quality with high precision. In this scenario, the unit of analysis is not a student; rather, it is a larger entity made up of students, teachers, educators, parents, administrators, and other stakeholders. Data from all these sources could be used to develop ML-based models to inform policy makers' decisions. Using ML algorithms, governments can build educational success models, starting with feature engineering (i.e. identifying all the important variables predictive of an outcome).

To work effectively, now and in the future, ML requires copious amounts of data, such as online accounts, learning management systems, and school databases. How to balance the use of all these data while protecting students' privacy is a concern as we move forward. The ethical issues of mass data collection and the overall use of ML and AI are current global concerns, but when dealing with vulnerable populations like young students, extra caution must be taken before ML can fully take off in education. Like any major advancement, the future of machine learning, and its benefits, will face hurdles we must surmount.

Concerns moving forward

As we move toward this new world of “smart” machines, the ethics of ML must remain at the forefront of progress. In general, computer scientists, researchers, educators, and educational policy makers who generate, put in use, and advance the technologies that are powered by ML must be mindful of the controversies to prevent their products from doing harm (Garrett et al., 2020). For instance, meticulous care must be given when both creating and training ML algorithms to ensure they remain unbiased. A misconception about AI and ML algorithms is that they are inherently unbiased because humans are not involved. However, humans have biases and humans are the ones writing the algorithms. Even well-intentioned people may possess implicit biases that unintentionally influence their designs (Bertrand and Mullainathan, 2004). More importantly, ML algorithms are trained on massive datasets that reflect the reality of human bias. Therefore, the algorithms can inherit those biases—e.g. racial or gender bias. Beyond that, human judgment is always involved in what is deemed worthy of being modeled by ML, and what is not. This may seem like a small issue, but even the underrepresentation of a single population can have a large impact during application. Consider the case of facial recognition algorithms powered by ML. Recent studies have shown that the accuracy of facial recognition software recognizing “darker” faces was lower compared to the accuracy of recognizing “lighter” faces (e.g. Buolamwini and Gebru, 2018). The reason for this discrepancy was due to the large number of lighter-skinned faces (i.e. about 85%) existing in the databases used to train the ML algorithm. Earlier, we provided two examples of using ML-powered facial recognition in classrooms (one for taking attendance and the other for building an engagement classifier). Such racial biases can sabotage those applications of ML in classrooms by mistakenly marking students of color as absent, or continually misidentifying a student's engagement due to idiosyncrasies associated with cultural differences.

ML algorithms can also be biased relative to gender. For example, Caliskan et al. (2017) found that natural language processing algorithms can inherit gender biases—either from the data that was used to train the algorithms or from ignoring such biases by the programmers. For instance, the word *nurse* is more frequently associated with the word *she* than with the word *he*. A biased model can perpetuate biases in those who interact with the biased environment; even the results of modern image searches can portray gender biases related to occupations (Kay et al., 2015). Allowing these skewed perspectives into the classroom can impair the struggle to reduce gender inequality.

There are some things we can do to reduce bias in data-driven, automated ML approaches. Ntoutsi et al. (2020) have suggested that we need to: (1) Understand bias relative to how it occurs in society and how it finds its way into the data used for training ML algorithms so that we can proactively address biases when creating algorithms and collecting data; and (2) Mitigate bias in each step of the ML decision making process. For example, we need to ensure that the ML algorithms are adequately trained on data from minority populations (i.e. gender- and race-balanced datasets) so that datasets provide a valid representation of all populations. Moreover, several researchers (e.g. Garrett et al., 2020; Saltz et al., 2019) have noted that it is in everyone's best interest to teach ethics in AI as part of computer science courses to make sure that future computer scientists (and others who will be writing the algorithms) are aware of ethical issues. But above all else, those who implement ML algorithms must retain “transparent classifiers which are interpretable on their own and exhibit predictive accuracy close to that of obscure models” (Ntoutsi et al., 2020, p. 8). Aggressive transparency, much like peer-review, helps establish a norm for public auditing of the algorithms that so intimately influence everyone's lives. And although there are ways to reduce the biases ML inherits from humans, we note that ML is not a panacea to all problems, particularly in educational systems. Thoughtful decisions about what to model (and why) need to be made prior to training ML algorithms.

Security (i.e. protection from hackers) and privacy (i.e. data anonymization) are also issues that need proper attention to ensure a successful future with ML (e.g. Mittelstadt and Floridi, 2016). When personal data on an individual are stored somewhere, people with harmful intentions may access the data (e.g. identity theft). Therefore, it is important to know how the data are stored, who owns the data, and how secure the data are. Regarding privacy, a quick resolution is to remove any identifiable information from the data, but this solution greatly diminishes an algorithm's ability to function as even just one's date of birth and zip code are enough to identify them (Mittelstadt and Floridi, 2016).

As mentioned previously, when facial recognition technology is used in classrooms and on campuses, concerns of privacy and abuse are quick to surface. However, we believe this trend is evident in the literature and the continued integration of ML (e.g. facial recognition) is a double-edged sword, offering great benefits alongside meaningful risks. If quick resolutions are non-solutions, then policies and legislature must ensure the security of students; for example, recommendations tend toward transparency and the ability to “opt-out” of having one's data collected. In short, legislation such as the General Data Protection Regulation passed in Europe and similar legislation passed in California possesses a spirit of security, privacy, and fairness that must extend to some extent to academia.

Finally, because new technologies appearing in the future may be more work and require additional learning for teachers who are already overwhelmed, we need research and development on user-friendly, easy-to-use tools that can attract teachers to use the tools. Moreover, professional education is needed to help teachers understand the strengths and weaknesses of the new tools. Any implementation of ML-powered systems in schools must be accompanied by comprehensive training for teachers to ensure they are fully in command of the power ML can give them, and aware of potential ethical issues in using them.

Conclusion

We first explained what AI and ML mean and how they relate to each other. Then, we focused on machine learning, its definition, history, and use in education, now and in the future. We concluded with a discussion of relevant concerns and issues related to the use of ML, especially in education, moving forward. What makes us confident that the future of education is bright is the amount of progress that has been made in the past several decades in terms of technology, learning sciences, computer science, psychology, psychometrics, and so on. No matter how far we eventually go in using ML in education, we need to remember that nothing can replace human-to-human and particularly teacher-student interactions.

The goal for ML should be to help—not replace—humans in classrooms. The algorithms that improve our daily online experiences can become extensions of the instructor, the administrator, and policymaker. ML can bring to one's fingertips answers to questions that just ten years ago required teams of researchers and decades of experience in the classroom. ML can automate and energize the classroom to the extent that the teacher is free to facilitate learning with a level of precision previously unattainable. Yes, caution must be taken, but with a careful hand, a watchful eye, and forethought informed by history, it is possible that we can press forward, propelled by technology, into a brave new world of education.

Acknowledgment

We would like to thank Ryan Baker and Angela Stewart for reviewing a draft of this paper.

Research has clearly shown that social-emotional competencies can be taught, that schools are appropriate places to teach them, and that SEL can make a positive difference in young people's lives.

Weissberg (2019, p. 65).

Recent years have witnessed amplified attention to the field of social and emotional learning (SEL) fueled by burgeoning research evidence indicating that promoting students' social and emotional competence in school improves not only their well-being and positive development, but such efforts lead to successful academic outcomes. Bolstered by a plethora of compelling empirical evidence showing that SEL programs and practices are successful in promoting students' social-emotional competence and deterring mental health problems and antisocial behaviors (e.g., Domitrovich et al., 2017; Weissberg et al., 2015) as well as cost-effective (Belfield et al., 2015), many school districts and jurisdictions in the US and internationally have strengthened their efforts to integrate SEL into the very fabric of schooling in efforts to educate the "whole child" and prepare young people for the 21st century (Darling-Hammond and Cook-Harvey, 2018).

Clearly, SEL is now a worldwide phenomenon and not just a passing fad, with SEL approaches and programs being implemented in countries throughout the world (Frydenberg et al., 2017; Humphrey, 2013; Torrente et al., 2015). Large scale organizations such as the World Bank, the World Health Organization (WHO), UNICEF, UNESCO, and the Organization for Economic and Cooperative Development (OECD) are joining in the call for a more explicit and intentional consideration of social and emotional competencies and social and emotional well-being into both education and health (e.g., OECD Education, 2018; Varela et al., 2013).

The overall aim of this chapter is to provide a summary of current theory and research in the field of SEL. The chapter begins by providing a rationale for the promotion of students' social-emotional competence in education, followed by a brief history of SEL, a definition of SEL, and a description of the social and emotional competencies that comprise SEL. Following a brief review of recent research that offers strong empirical support for an SEL approach is put forth. Next, essential ingredients of a systemic approach to SEL are delineated. The chapter ends by offering some future directions conclusions on how an understanding of SEL has implications for the transformation of education.

SEL: rationale and definitions

Why now? The need for SEL

My own work on SEL originated during my time as a middle school teacher and a teacher at an alternative high school for youth deemed “at risk” for high school completion during the 1980s. My students inspired me, taught me, and coached me to learn from them about what it takes to create an educational context in which they could learn and flourish. The phrase that resounded for me was “Students don’t care how much you know until they know how much you care.” It was at that time that I learned that my success as a teacher relied on not only educating my students’ minds, but educating their hearts as well. And to do so required that I pay explicit attention to cultivating their social-emotional competencies, including their ability to be aware of their strengths and challenges, identify and regulate their emotions, show empathy and compassion for others, and seek help when they needed it. Nonetheless, what was missing at that time was the field of SEL and the science behind it, so I had limited information—I worked on instinct and had little from which to draw from my teacher training or support from the educators in my school context. It was during those years that I also realized that so many of the social and emotional problems that I saw in my students were preventable. This inspired me to enroll in graduate school so that I could explore the research on prevention and the promotion of students’ social and emotional competencies to better understand the social and emotional dimensions of teaching and learning. This work inspired a professional career that has spanned over 30 years in which I have sought to answer one central question: What are the ways that we can create educational contexts that foster students’ social and emotional competencies, such as empathy, compassion, altruism, and resiliency so that all young people can thrive and reach their optimal potential?

SEL and neuroscience: we feel therefore we learn

Many of the recent discussions on education and educational reform have emphasized that young people’s social, emotional, and academic development are inextricably linked (Cantor et al., 2018; Jones and Kahn, 2017). These conjectures draw strong support from research in the field of social neuroscience. As Immordino-Yang and Damasio (2007) assert, “The aspects of cognition that are recruited most heavily in education, including learning, attention, memory, decision making, motivation, and social functioning, are both profoundly affected by emotion and in fact subsumed within the processes of emotion” (p. 7). Stated simply, how we feel affects how and what we learn.

Recent innovations in neuroscience that emphasize the vital role of social experiences on brain development and learning support the explicit integration of SEL into education (Immordino-Yang et al., 2019). Groundbreaking new research that has emerged during the last half of the 20th century challenges pre-existing beliefs about the brain’s malleability by demonstrating that the brain is changeable (or “plastic”) to experience across childhood and adolescence, and even into adulthood (Baltes et al., 2006; Pascual-Leone et al., 2005). Similarly, research from the field of developmental cognitive neuroscience (Diamond, 2012), indicates that social and emotional skills can be taught across the life span and are viewed as more malleable than IQ.

Escalating mental health problems in children and youth

An increased emphasis on the role of schools in promoting students’ social and emotional competence and well-being reflects, in part, growing concerns about the problems facing youth today, such as declining academic motivation (Roeser and Eccles, 2014), increasing school bullying and aggression (Hymel and Swearer, 2015), an escalating mental health crisis (Jones et al., 2022), and decreases in well-being in youth exacerbated by the Covid-19 pandemic (Gadermann et al., 2022; Luthar et al., 2021).

The crisis of children’s mental health and rising disparities in educational outcomes has risen to the forefront of national consciousness with the release of the most recent US Surgeon General’s Advisory in December 2021. The Advisory calls attention to the rising mental health issues of young people and disparities across subpopulations in the US. It then outlines a whole-society approach for tackling the problem and includes a set of recommendations designed to prevent these challenges and bolster children’s well-being. One of the primary recommendations outlined is to “support the mental health of children and youth in educational, community, and childcare settings,” which involves, “creating positive, safe, and affirming educational environments” and “expanding programming that promotes healthy development (such as social and emotional learning)” (p. 13). To support the well-being and mental health of students, the Advisory also encourages policymakers and schools to undertake efforts designed to promote the “mental health of all school personnel” (p. 20). For instance, the recommendations suggest regular assessments of staff well-being and the integration of wellness initiatives into professional development for school staff. The Advisory proports that these efforts will directly benefit school personnel, while, at the same time, help to foster teachers’ social and emotional competencies (SECs, e.g., empathy and compassion)—competencies that are needed to create positive learning environments that can promote student well-being and healthy development (Lever et al., 2017; US Dept. of Education, 2021). Furthermore, other policy makers and advocacy groups in the US have called for the increased training of teachers in SEL so that teachers are better equipped to support the development of students’ SECs and well-being throughout the COVID-19 crisis and beyond (Walker, 2020).

Widespread support for SEL

There now exists consensus among parents, teacher, principals, and the general public that SEL should be integrated into schooling. Indeed, recent research indicates that the myopic focus on academics as the sole purpose of education appears to be shifting, with support for SEL from parents (Edge Research, 2018; PDK International, 2017) and the general public (Bushaw and Lopez, 2013;). Results from the 2013 PDK/Gallup Poll of the Public’s Attitudes Toward Public Schools indicates that most Americans agree that

public schools should teach students a full range of social, emotional, and cognitive competencies, including how to set meaningful goals (89%), communication skills (94%), how to collaborate on projects (84%), and character (76%).

Similarly, teachers confirm that SEL is an essential part of education. For example, a nationally representative survey published by Civic Enterprises and Peter D. Hart Research Associates of more than 600 teachers (Bridgeland et al., 2013) illustrates this point. Their report showed that the vast majority of preschool to high school teachers believe that social and emotional skills are teachable (95%) and that promoting SEL will benefit students from both rich and poor backgrounds (97%) and will have positive effects on their school attendance and graduation (80%), standardized test scores and overall academic performance (77%), college preparation (78%), workforce readiness (87%), and citizenship (87%). Additionally, these same teachers reported that, in order to implement and promote SEL effectively in their classrooms and schools, they need strong support from district and school leaders. These findings are important because they demonstrate that, although there is a readiness among teachers to promote SEL, there is a need for systemic supports for implementation at the district level. Similarly, a 2019 Rand Cooperation report by Hamilton, Doss, and Steiner echoes strong support for SEL, notably among both principals and teachers. Their survey revealed that a large majority of principals identified SEL as a top priority and that both principals and teachers identified a wide range of SEL skills as important (Hamilton et al., 2019).

Despite resounding support for SEL, it is not without its critics. Most recently, prominent scholars and education leaders have voiced their concerns about the rapid interest and implantation of SEL throughout the US (e.g., Finn and Hess, 2019; Hamilton and Schwartz, 2019; Hess, 2019; McShane, 2019; National Commission on Social, Emotional, and Academic Development, 2018; Starr, 2019). One frequent point of criticism for SEL is in regard to its definition. Some argue (e.g., Finn and Hess, 2019; Starr, 2019) that the definition for SEL is ambiguous and can mean many different things to different people. In a thoughtful and comprehensive response to concerns about SEL, Shriver and Weissberg (2020) posit that “Just like every other widely used term in K-12 education—deeper learning, mastery learning, collaborative learning, instructional leadership, and so on—SEL will no doubt be misunderstood by some people and misused by others trying to cash in on its popularity” (p. 53). They note that while the organization in which they both are members—the Collaborative for Academic, Social, and Emotional Learning or CASEL—has worked for over 25 years to define SEL, no one organization owns a definition of SEL, therefore some definitional ambiguity is inevitable. Despite this, Shriver and Weissberg contend that there is widespread agreement among leaders in the SEL movement on a set of foundational principles. Specifically, any SEL Framework should include a focus on both intrapersonal and interpersonal skills and attitudes; be developmentally appropriate and culturally sensitive; be grounded in empirical research; and support implementation and evaluation programming by offering practitioners resources that are evidence-based (Blyth et al., 2019). Undoubtedly, debates about SEL will continue—what is needed for the field to grow and flourish are productive and open conversations in which different points of view can provide an impetus for innovation and new knowledge.

A brief history of SEL

Although the term “SEL” is relatively recent—dating back almost 30 years—the attention to children’s social and emotional development in relation to education dates back much longer. For instance, centuries ago Aristotle posited that, “Educating the mind without educating the heart is no education at all” emphasizing that the aim of education should not solely focus on the mastery of subject content areas such as reading, writing, math, science, and social studies, but should include an explicit and intentional focus on teaching students social and emotional competencies, including empathy and compassion. More recent instantiations of SEL can be traced back to the early 1900s with John Dewey’s (1916) progressive education efforts that focused on the promotion of students’ social responsibility, Maria Montessori (1912) schools that emphasized child-centered education and a focus on whole child education—cognitive, social, emotional, and physical development, and Jane Addams (2002) focus on engaged citizenship and student agency and autonomy which aligned with Dewey’s focus.

The theoretical and empirical work in SEL related fields in particular can be traced back to the beginning of the 20th century. Osher et al. (2016), in their recent review of the genesis of SEL, noted that “The roots of SEL are intellectually diverse and politically nonpartisan” (p. 647). In their review, they trace back the roots of SEL to educational reform efforts in the early part of the 20th century (including John Dewey and Jane Addams) to the “Mental Hygiene Movement” with its presage attention to prevention of mental illness, and to Thorndike’s (1920) conception of “social intelligence.” Over the course of the 20th century, the shift to understanding the contextual influences that shape child development began to emerge and researchers such as Bronfenbrenner and his “bioecological model of human development” (1979; Bronfenbrenner and Morris, 2006) espoused the importance of taking into account the nature and levels of context as influencers on child development. Bronfenbrenner’s “bioecological model of human development” led to increased attention to the implementation of systemic interventions in the 1980s and 1990s (Elias et al., 1997).

The growth of SEL work was gradual and somewhat intermittent across the century but expanded markedly in the 1990s when researchers such as Salovey and Mayer (1990) began to work in the new field of “emotional intelligence.” Their work both built upon and expanded the work of Howard Gardner’s (1983) “multiple intelligences” and Robert Sternberg’s (1985) practical intelligence, challenged typical definitions of intelligence by showing the critical roles of emotion and motivation in predicting life success.

In 1995 the publication of Daniel Goleman’s book *Emotional Intelligence: Why It Can Matter More than IQ* catalyzed the field by making SEL a term known by researchers and the larger public. At the same time that interest in SEL was growing, there was an accumulating research base regarding the effectiveness of programs to prevent problem behavior and promote healthy development

coupled with a growing knowledge base on the importance of school climate to promote students' healthy relationships, achievement, and school connectedness, and prevent dropout (e.g., [Thapa et al., 2013](#)). Similarly, growing concerns around problems such as bullying and school shootings spurred an urgency for the creation and implementation of school programs focused on promoting safe and supportive school environments ([Dwyer and Osher, 2000](#); [Dwyer et al., 1998](#)).

Today, SEL has been characterized in a variety of ways, often being used as an organizing framework for an array of promotion and prevention efforts in education and developmental science, including conflict resolution, cooperative learning, bullying prevention, and positive youth development ([Schonert-Reichl and Weissberg, 2015](#); [Weissberg et al., 2015](#)).

What is SEL?

Social and emotional learning, or SEL, involves evidence-based programs, practices, and policies through which children, youth, and adults acquire the competencies to recognize and manage emotions, develop caring and concern for others, establish positive relationships, make responsible decisions, and handle challenging situations effectively ([Weissberg, 2019](#); [Weissberg et al., 2015](#)). That is, SEL programs and practices teach the personal and interpersonal competencies we all need to handle ourselves, our relationships, and our work effectively and ethically. Accordingly, SEL is aimed at helping children and even adults develop fundamental skills for success in school and life.

SEL builds from work in child development, classroom management, prevention, and emerging knowledge about the role of the brain in self-awareness, empathy, social-cognitive growth (e.g., [Best and Miller, 2010](#); [Goleman, 2006](#); [Immordino-Yang et al., 2019](#)), and focuses on the skills that allow children to calm themselves when angry, make friends, resolve conflicts respectfully, and make ethical and safe choices. In short, SEL competencies comprise the foundational skills for positive health practices, engaged citizenship, and school success ([Weissberg et al., 2015](#)). SEL is sometimes called "the missing piece" in education because it represents a part of education that is inextricably linked to school success but has not been explicitly stated or given much attention until relatively recently. SEL emphasizes active learning approaches in which skills can be generalized across curriculum areas and contexts when opportunities are provided to practice the skills that foster positive attitudes, behaviors, and thinking processes.

In SEL, social-emotional competencies are viewed as "mastery skills" underlying virtually all aspects of human functioning. Moreover, SEL emphasizes active learning approaches in which skills can be generalized across curriculum areas and contexts when opportunities are provided to practice the skills that foster positive attitudes, behaviors, and thinking processes.

SEL frameworks

The SEL landscape is replete with SEL frameworks. [Berg et al. \(2017\)](#) conducted an extensive review of frameworks related to the social and emotional (SE) competencies among youth between the ages of 6–25 years. Through their examination of reports, papers, and discussions with experts across a range of fields, including economics and health, they identified 136 frameworks across 14 areas of study, including areas such as Positive Youth Development, Resilience, Character Education, School-Based Competency Development, Public Health, Mental Health, Mindfulness to name a few (see [Berg et al., 2017](#), for a full description of their approach and findings). One central finding that emerged in their review was "that different terms are used for competencies that have similar definitions, and that the same terms are used for competencies that have different definitions" (p. 40). Their work underlines the importance of conceptual clarity when identifying and analyzing appropriate SEL frameworks.

CASEL's SEL framework

The Collaborative for Academic, Social, and Emotional Learning (CASEL; www.casel.org) a nonprofit organization in Chicago, IL, is one of the organizations at the forefront in North American and international efforts to promote SEL. Founded in 1994 by Daniel Goleman and Eileen Rockefeller Growald, its mission is to advance the science of SEL and expand evidence-based, integrated SEL practices as an essential part of preschool through high school education.

CASEL's SEL framework is one of the most recognized SEL frameworks across the world (see [Fig. 1](#)). The framework takes a systems approach that includes a set of social-emotional competencies that underlie effective and successful performance for social roles and life tasks, drawing from extensive research in a wide range of areas, including social neuroscience and methods of learning and instruction. The concentric circles that surround the five social-emotional competencies—notably, communities, families and caregivers, schools, and classrooms—are the key settings in which SEL promotion occurs. These serve as an organizing framework for coordinating policies and practices that students experience both inside and outside of the classroom. The five social-emotional competencies identified by CASEL are described in more detail below ([Weissberg et al., 2015](#); www.CASEL.org):

The CASEL Five.

1. *Self-awareness*: The abilities to identify and recognize one's own emotions, thoughts, and influences on behavior, including recognizing one's own strength and challenges, being aware of one's own goals and values, possessing a well-grounded sense of self-efficacy and optimism, and having a growth mindset that one can learn through hard work. High levels of self-awareness require recognizing how thoughts, feelings, and actions are interconnected. Dimensions of self-awareness include: integrating personal and social identities, identifying personal, cultural, and linguistic assets, demonstrating honesty and integrity, linking feelings, values, and thoughts, examining prejudices and biases, and developing interests and a sense of purpose.
2. *Self-management*: The abilities to regulate one's emotions, thoughts, and behaviors effectively, including stress management, delaying gratification, impulse control, motivating oneself, and persevering through challenges to achieve personal and

- educational goals. It also includes self-management within social interactions. Other skills include: using planning and organizational skills, showing the courage to take initiative, and demonstrating personal and collective agency
3. *Social awareness*: The abilities to take the perspectives of others—including those who come from a different background and culture, to empathize with others, understand social and ethical norms, and to recognize resources and supports in family, school, and community. Other social awareness competencies include: recognizing strengths in others, demonstrating empathy and compassion, showing concern for the feelings of others, understanding and expressing gratitude, identifying diverse social norms, including unjust ones, recognizing situational demands and opportunities, and understanding the influences of organizations/systems on behavior.
 4. *Relationship skills*: The abilities to establish and maintain healthy and supportive relationships and to effectively navigate settings with diverse individuals and groups, communicate clearly, listen actively, cooperate, negotiate constructively during conflict, solve problems with others, navigate settings with differing social and cultural demands and opportunities effectively, demonstrate cultural competency, practice teamwork and collaborative problem-solving, resist social pressure, show leadership in groups, and to offer and seek help when needed, and stand up for the rights of others.
 5. *Responsible decision making*: This includes the knowledge, skills, and attitudes to make constructive choices regarding one's own behavior and social interactions, taking into account safety concerns, ethical standards, social and behavioral norms, consequences, and the well-being of self and others, and to evaluate the benefits and consequences of various actions for personal, social, and collective well-being. Additional examples include: demonstrating curiosity and open-mindedness, identifying solutions for personal and social problems, learning to make a reasoned judgment after analyzing information, data, facts, recognizing how critical thinking skills are useful both inside and outside of school, reflecting on one's role to promote personal, family, and community well-being, and valuating personal, interpersonal, community, and institutional impacts.

What is transformative SEL?

Until recently, the definition of SEL did not include an explicit focus on considering the cultural and racial differences, privilege, and inequities that exist in schools (Jagers et al., 2019). To address this and to help advance the research agenda for the next generation by focusing on SEL in the service of equity and excellence, an expanded definition of SEL has been put forth by Jagers et al. (2019). The concept “transformative SEL” is the process whereby young people and adults build strong, and respectful relationships that facilitate co-learning to critically examine root causes of inequity and to develop collaborative solutions that lead to personal, community, and societal well-being. This new definition sets a vision for what high-quality systemic SEL is and how it might be achieved. Moreover, this form of SEL is necessary to meet the growing political, economic, and health challenges we face in the US and around the world.

Transformative SEL competencies focus on identity, intersectionality, agency, belonging and engagement as central to furthering social-emotional development and achieving equity in education (Jagers et al., 2019). Strategies identified as promoting these

Fig. 1 The collaborative for academic, social, and emotional learning (CASEL) framework.

transformative social-emotional competencies are culturally infused SEL skill development, project-based learning and youth participatory action research.

Also relevant to a discussion of an equity in transformative SEL are disciplinary approaches. Restorative practices for resolving conflict and behavioral issues offer an inclusive approach to counteract exclusionary, punitive measures that disproportionately marginalize students of color (Gregory and Fergus, 2017). Research evidence suggests that restorative approaches teach students skills for conflict resolution and help students become better integrated into the school community (Morrison, 2013; Wearmouth et al., 2007).

What is systemic SEL?

Because virtually all children go to school during key developmental years, schools are important contexts for fostering children's positive social and emotional competencies. Widely acknowledged is that efforts to make SEL an enduring aspect of education, need to include SEL at every level of the school, including school leadership, teaching and learning, and with families and community (see Mahoney et al., 2020). As recently espoused by Mahoney et al. (2020, p. 1),

Systemic SEL is an approach to create equitable learning conditions that actively involve all Pre-K to Grade 12 students in learning and practicing social, emotional, and academic competencies. These conditions require aligned policies, resources, and actions at state and district levels that encourage local schools and communities to build the personal and professional capacities of adults to: implement and continuously improve evidence-based programs and practices; create an inclusive culture that fosters caring relationships and youth voice, agency, and character; and support coordinated school-family-community partnerships to enhance student development.

Especially noteworthy in the above description of systemic SEL is that any approach to promote social and emotional competence in students must consider the interpersonal and intrapersonal capacities of the adults in the education system.

CASEL has developed a set of guidelines and school and school district resources for implementing SEL at the level of the system (www.CASEL.org). For example, for schools, CASEL has put forth "10 Indicators of Schoolwide SEL" that are evidence-based, and include: (1) Explicit SEL instruction, (2) SEL integrated with academic instruction, (3) Youth voice and engagement, (4) Supportive school and classroom climate, (5) Focus on adult SEL and relationships, (6) Supportive discipline, (7) A continuum of integrated supports, (8) Systems for continuous improvement, (9) Authentic family partnerships, and (10) Aligned community partnerships. Full descriptions of these, along with a rubric for assessing them, and many other resources from CASEL for integration of SEL schoolwide, can be found at: <https://schoolguide.casel.org/>

SEL: the research evidence

SEL skills in childhood predict academic achievement and adult success

A growing body of literature supports the premise that children's social-emotional competence not only predicts success in school (e.g., Oberle et al., 2014; Wentzel, 1993), but also predicts a range of important outcomes in late adolescence and adulthood, including physical health, substance dependence, and overall well-being (Moffitt et al., 2011). Recognizing the interrelationship between social-emotional competencies and academic success, researchers have argued that fostering positive social and emotional development may be key to enhancing academic growth (see Greenberg et al., 2003; Zins et al., 2004).

One early study that was pioneering in its design and approach to demonstrating the critical role of social-emotional competencies in predicting students' academic success, is from Wentzel (1993) titled "Does Being Good Make the Grade?" In her study of 423 sixth and seventh graders, Wentzel (1993) found that students' prosocial classroom behaviors, such as helping, sharing, and cooperating, were better predictors of academic achievement than were their standardized test scores, even after taking into account academic behavior, teachers' preferences for students, IQ, family structure, sex, ethnicity, and days absent from school. Similarly, in a longitudinal study of 294 Italian children, Caprara et al. (2000) found that prosocial behavior in third grade (average age 8.5 years) as rated by self, peers, and teachers, significantly predicted both academic achievement (explaining 35% of the variance) and social preference (explaining 37% of the variance) 5 years later when children were in eighth grade. Most interestingly, this "prosocialness" score, which included cooperating, helping, sharing, and consoling behaviors, significantly predicted academic achievement five years later, even after controlling for third grade academic achievement. In contrast, early academic achievement did not contribute significantly to later achievement after controlling for effects of early prosocialness. Collectively, these correlational studies, demonstrate the importance of social-emotional competencies in predicting short-term and long-term success.

In a short-term, longitudinal study of 441 sixth grade Canadian students, Oberle et al. (2014) examined the association between social and emotional competence and academic achievement in early adolescents. Social-emotional competence in grade 6, operationalized in terms of both self-reports of social responsibility goals and teacher assessments of frustration tolerance, assertive social skills, task orientation, and peer interaction, were evaluated as predictors of student academic achievement test scores in math and reading grade 7. As hypothesized, teacher-reports of students' social-emotional competencies significantly predicted higher scores in math and reading in seventh grade. Self-reported social-emotional competence in grade 6 was a significant predictor of grade 7 reading scores for boys but not girls. Although more research is needed regarding the link between SEL and academic

achievement, there is a confluence of empirical evidence suggesting that, if we want students to be successful in school, efforts should be made to teach SEL intentionally and explicitly.

In addition to playing a crucial role in predicting academic success, recent longitudinal research also documents links between children's social and emotional skills and later success in adulthood. Jones et al. (2015), for instance, examined the degree to which late adolescent and early adult outcomes were predicted by teacher ratings of children's social-emotional competence measured many years earlier, when children were in kindergarten, following 753 kindergarten children longitudinally, 13–19 years later. Kindergarten teacher ratings of children's prosocial skills (getting along with others, sharing, cooperating) were found to be significant predictors of whether participants graduated from high school on time, completed a college degree, obtained stable employment in adulthood, and were employed full time in adulthood. Moreover, kindergarten children who were rated by their teachers as high in prosocial skills in kindergarten, were less likely as adults to receive public assistance, live in or seek public housing, be involved with police, placed in a juvenile detention facility, or arrested. Early social competence inversely predicted days of binge drinking in the last month and number of years on medication for emotional or behavioral problems during high school. Given these findings, the authors emphasize the importance of assessing young children's social and emotional competence early on and contend that these "softer" skills can be more malleable than IQ or other cognitive measures and, hence are important contenders for intervention.

In another notable longitudinal study Moffitt et al. (2011) followed a cohort of 1000 children from birth to 32 years in New Zealand, assessing children's self-control across the ages of 3, 5, 7, 9, and 11 years via reports from researcher-observers, teachers, parents, and the children themselves. Self-control in childhood was found to predict physical health, substance dependence, personal finances, and criminal offending in adulthood, even after taking into account intelligence, social class, and problems the children had in adolescence (e.g., smoking, school drop-out). The authors concluded that focusing on the promotion of children's self-control "might reduce a panoply of societal costs, save taxpayers money, and promote prosperity" (p. 1). Thus, results from several recent longitudinal studies examining the association between early SEL skills and later adult adjustment suggest that, in the long run, higher levels of social and emotional competence can increase the likelihood of high school graduation, financial success, mental and physical health, and reduce criminal behavior.

Social and emotional skills are malleable—they can be taught

One approach to promoting the well-being and success of our young people and to ensure that they grow into productive adults is to identify the cognitive and social-emotional knowledge, skills, attitudes, and values that are considered to be "malleable"—that is, those that can change and be promoted through education and other experiences. Although the previous terminology in psychology referred to many of these constructs as "traits," hence conveying a sense of immutability or permanence, current descriptions identify these constructs as "skills" because they can be shaped and changed over the life cycle.

As described earlier, SEL is grounded in research from developmental cognitive neuroscience (e.g., Diamond, 2012) that indicates that social and emotional skills can be taught across the life span and are more malleable than IQ. Immordino-Yang et al. (2019) posit that although the malleability of the brain can be changed by experience through the lifespan, there remain periods across human development for which the brain experiences is more actively changing. These periods include the prenatal period through childhood, early adolescence, transition to parenthood, and old age. This information is particularly important when making decisions about SEL programming during the elementary, middle, and high school years.

Perhaps some of the most compelling evidence for the malleability of students' social-emotional competencies comes from a meta-analysis conducted by Durlak et al. (2011) of 213 school-based, universal SEL programs involving 270,034 students from kindergarten through high school. Students in SEL programs, relative to students who did not receive an SEL program, were found to demonstrate significantly improved social-emotional competencies, attitudes, and behavioral adjustment (increased prosocial behavior and decreased conduct problems and internalizing problems). SEL students also outperformed non-SEL students on indices of academic achievement by 11-percentile points. Durlak et al. also found that classroom teachers and other school personnel effectively implemented SEL programs. Thus, SEL programs can be easily incorporated into routine school practices and do not require staff from outside the school for successful delivery. Taken together, these results provide strong empirical evidence for the "value-added" of SEL programs in fostering students' social and emotional skills, attitudes, and behaviors, and also counter the claim that taking time to promote students' SEL would be detrimental to academic achievement.

Similar results were obtained in another meta-analysis of 75 recently published studies of SEL programs conducted by Sklad et al. (2012). That is, Sklad et al. found that universal, school-based SEL programs had significant positive effects on seven outcomes: social-emotional skills, prosocial behavior, positive self-image, academic achievement, antisocial behavior, mental health problems, and substance abuse. Not surprisingly, the most positive effects were found for social-emotional skills, with an effect size of 0.70. In other words, students participating in SEL programs had social-emotional skills 0.7 of a standard deviation higher than comparison students, indicating that the average SEL program student had better social-emotional skills than 76% of non-SEL students. Moderate effect sizes (program effects of nearly a half of a standard deviation) emerged for four of the outcomes: academic achievement, positive self-image, prosocial behavior, and antisocial behavior. As for follow-up effects, the largest effects were found for academic achievement, followed by substance abuse.

SEL skills are durable

Do students maintain their SEL competencies after the SEL program has ended? Findings from [Durlak et al. \(2011\)](#) meta-analysis described above provide additional support for the durability of effects of SEL programming on students' social and emotional competencies. Durlak and colleagues examined a smaller group of 33 interventions that included follow-up data (an average follow-up period of 92 weeks) and found that the positive effects remained statistically significant, although the effect sizes were smaller.

Research by [Hawkins et al. \(2008\)](#) documented the long-term positive effects of multi-year SEL programming on student outcomes. Specifically, Hawkins et al. found significantly reduced diagnosable mental health disorders (e.g., major depression, generalized anxiety disorder) at age 24 and age 27, which was 12 and 15 years after their SEL intervention had ended. Their results also showed intervention effects indicating better educational and economic achievement among those individuals who received the SEL intervention in contrast to those who did not. Although more research is clearly needed, Hawkins et al.'s research provides important evidence about the potential long-term benefits of well-designed and well-implemented SEL interventions.

More recently, [Taylor et al. \(2017\)](#) conducted a systematic review to address the relative paucity of evidence on the long-term effectiveness of SEL programming in enhancing positive student outcomes. This review is important because it addresses a critical question regarding the cost-benefit of investment in SEL programs, informing allocation of resources for SEL in school budgets. A total of 82 research studies evaluating school-based, universal SEL programs involving 97,406 ethnically and socio-demographically diverse students, from kindergarten to high school and in urban and rural settings were reviewed. Results demonstrated that students who had received an SEL intervention continued to show increases in social-emotional skills, positive behaviors and academic achievement, and decreases in conduct problems, emotional distress, and drug use up to almost four years after program completion, in contrast to those students who did not receive an SEL intervention.

SEL: the essential ingredients

As noted earlier, several organizing frameworks have been proposed for SEL, each one outlining various components that influence SEL—such as school culture and climate, and teachers' pedagogical skills—and each framework identifies similar student outcomes, such as improved academic achievement and social and emotional competence. Hence, in addition to focusing on specific instruction in social and emotional skills, SEL is a process of creating a school and classroom community that is caring, supportive, and responsive to students' needs. Moreover, effective SEL interventions and skill development occurs when teachers possess the requisite social and emotional skills to create an environment that is safe, caring, supportive, and well-managed, and have the social-emotional competencies and knowledge to implement SEL programs effectively.

To create a parsimonious depiction of a systemic approach to SEL, I contend that there are three distinct and interrelated dimensions: (1) The learning context, (2) SEL of students, and (3) SEL of teachers. As illustrated in [Fig. 2](#), these three dimensions are portrayed in a circle to illustrate the interconnectedness of each dimension to each other and to highlight that each dimension is influenced by, and influences, the other dimensions. Each one is discussed in turn below.

Ingredient 1: the learning context

Children can learn and thrive when they are in school and classroom contexts in which they feel safe, secure, connected, and cared for—contexts in which their social emotional competence and academic growth is nurtured and cultivated ([Jones and Kahn, 2017](#)). Conversely, stressful classroom contexts can thwart children's learning and jeopardize their mental health—leading them on a trajectory toward educational failure and problem behaviors ([Domitrovich et al., 2017](#); [Sauve and Schonert-Reichl, 2019](#)). Classrooms and schools operate as systems, and decades of research suggest that the unique culture and climate of classrooms and schools affects how and what students learn (e.g., [Thapa et al., 2013](#)). School culture refers to a general set of norms, beliefs, and practices or "the way things are done around here" ([Hemmelgarn et al., 2006](#)), whereas school climate "reflects norms, goals, values, interpersonal relationships, teaching and learning practices, and organizational structures" ([National School Climate Council, 2007](#), p. 4). Culture and climate, in combination, influence the interactions and relationships among administrators, teachers, school staff, and students and their approaches to teaching and learning ([Gottfredson et al., 2005](#)). Therefore, any approach to promoting SEL needs to take into account both school culture and climate and systematically and intentionally embed SEL into every dimension of a school.

SEL interventions and skill development should occur within supportive classroom and school environments, as well as help to create such a climate. Additionally, successful SEL-related school and classroom activities foster active student voice in decision-making, problem solving, and engagement in lifelong learning. Research also has shown that effective programs provide repeated opportunities to practice new skills and behaviors within the program structure and to apply them in real-life situations. That is, providing opportunities to practice within classroom lessons is important, but actual opportunities to practice in real-life situations are likely to have even more impact ([Durlak et al., 2011](#); [Weare and Nind, 2011](#)). Communication styles, high performance expectations, classroom structures and rules, school organizational climate, commitment to the academic success of all students, district policies, and parental and community involvement are all important components of an SEL approach in the learning context.

Fig. 2 The essential ingredients of SEL.

Ingredient 2: SEL of students

Promoting the SEL students includes several dimensions, including explicit SEL instruction through evidence-based SEL instruction, infusion of SEL into academic subjects, and providing students with opportunities for voice and agency. In 2003 CASEL published the results of a careful review of 80 SEL programs for kindergarten through to 12th grade entitled, *Safe and Sound: An Educational Leader's Guide to Evidence-Based Social and Emotional Learning (SEL) Programs*. This groundbreaking review provided educators with practical information on the features of different programs that could help them select programs most relevant and suited for their particular needs. In 2013, CASEL reviewed hundreds of SEL preschool and elementary school programs and identified dozens of programs that met high standards for program design, implementation supports, evidence of effectiveness, and applicability to specific grades. To be included in the 2013 CASEL Guide (CASEL, 2013) and designated as "SElect", the program had to meet three criteria: (a) be a well-designed classroom-based program that systematically promotes students' social and emotional competence, provides opportunities for practice, and offers multi-year programming, (b) deliver high-quality training and other implementation supports, including initial training and ongoing support to ensure sound implementation and, (c) be evidence-based with at least one carefully conducted evaluation that documents positive impacts on student behavior and/or academic performance. The 2013 CASEL Guide summarizes objective information about the characteristics of these nationally available, multi-year programs via a "consumer report" format that is clear and easy to read. Included in the Guide is information on SEL programs identified as CASEL SElect programs designed for preschool through elementary school students. A guide for middle school and high school programs was released by CASEL in 2015. Moreover, the CASEL Program Guide continues to be updated as new SEL programs are reviewed. Similar efforts to evaluate the effectiveness of various SEL programs are available on the University of Colorado Blueprints website (www.blueprintsprograms.com) and on the Public Health Agency of Canada's Violence Prevention Portal (<http://cbpp-pcpe.phac-aspc.gc.ca/public-health-topics/violence-prevention/>).

With regard to SEL program implementation, it is also critical to keep in mind the critical elements of effective SEL programs. In this vein, in their meta-analyses, Durlak et al. (2011) provided evidence that SEL programs promote better student outcomes when program implementers incorporate four elements represented by the acronym SAFE:

- (1) *Sequenced*: connected and coordinated set of activities to foster skills development;
- (2) *Active*: active forms of learning to help students master new skills;
- (3) *Focused*: a component that emphasizes developing personal and social skills; and
- (4) *Explicit*: targeting specific social and emotional skills.

The effective *implementation* of an SEL program plays a crucial role in influencing student outcomes. Unfortunately, some well-designed SEL programs do not promote positive student outcomes, often due to variability in way the program is implemented in the "real world" setting of a school and/or classroom. When implementing an established SEL program that has been shown to be effective, it is important for educators to recognize the importance of completing all lessons and activities in the program (dosage) and doing so as designed by the program developers (fidelity) in order to maximize the likelihood of success of the program in their own classroom environment.

Ingredient 3: SEL of teachers

Teachers are the engine that drives SEL programs and practices in classrooms and school (Schonert-Reichl, 2017) and teachers own SEL competence and well-being plays a critical role in influencing the learning context and the infusion of SEL into classrooms and schools (Jones et al., 2013). Researchers have shown that promoting the social and emotional competencies and of students is most effective when explicit attention is given to all levels of the system, including educator SEL (Mahoney et al., 2020).

Classrooms with warm teacher-child relationships facilitate deep learning among students (Merritt et al., 2012), and when children feel comfortable with their teachers and peers, they are more willing to grapple with challenging material and persist at difficult learning tasks. Conversely, when teachers poorly manage the social and emotional demands of teaching, students demonstrate lower levels of performance and on-task behavior (Marzano et al., 2003). Hence, it is essential that efforts are made to support the development of teachers' SEL competencies in order to optimize their classroom performance and their ability to promote SEL in their students (Jennings and Frank, 2015).

Caring teachers: strategies for the classroom

A caring teacher can transform the school experience, especially for students who face enormous difficulties, such as dropping out or dysfunctional home lives. The quality of teacher-student relationships is critical for children's academic achievement as illustrated by the work of Maldonado-Carreno and Votruba-Drzal (2011). Using data from the NICHD Study of Early Childcare of 1364 children from kindergarten through fifth grade, they found that increases in the quality of teacher-student relationships were associated with concomitant improvements in teacher-reported academic skills. Moreover, these relations remained unchanged as children progressed from kindergarten through fifth grade.

Some explicit strategies for fostering positive student-teacher relationships and caring classrooms include:

- Greeting students every day as they enter the classroom, with intentional efforts to have a brief *positive* conversation with them (e.g., noticing their new backpack or shoes) (Cook et al., 2018).
- Getting to know each student and the lives they live, learning about their strengths, challenges, interests and dreams. This could be done at the beginning of the school year, through individual interviews with each student. Teachers can also ask students about what they, as teachers, can do to help students learn and thrive in school.
- Actively listening to students to show you care. Authentic listening is demonstrated by hearing your students and then checking back with them to make sure you understand. Such interactions help to develop a trusting relationship between teachers and students.
- Asking students for advice and feedback as well as help when needed. For example, teachers can ask for help in setting up the classroom (e.g., what to put on the classroom bulletin boards, how to arrange the seating, how to organize activity centers), giving students a voice in the nature and organization of their physical environment. Through regular class meetings, teachers can engage students in developing the rules for the classroom and in creating a positive classroom environment. By considering student feedback, teachers demonstrate that student opinions and experiences are valued, and helps to create a classroom culture in which students feel safe to ask questions and take chances, enhancing the development of their SEL skills as well as their academic success.

Teacher stress and stress contagion

Clearly, teachers play a vital role in cultivating a positive and nurturing context that fosters students' social, emotional, and academic success (e.g., Braun et al., 2020). Nonetheless, teachers' stress and burnout can undermine their efforts to create an optimal context for healthy development and learning for their students. Decades of research have demonstrated that teaching is one of the most stressful professions in the human service industry (Montgomery and Rupp, 2005). Chronic work stress and exhaustion among teachers is associated with negative changes in biological indicators of stress as well with recent research showing that teachers who report chronic stress demonstrate atypical patterns of physiological stress reactivity as assessed via diurnal cortisol (Katz et al., 2016; Wolfram et al., 2013). Moreover, mounting evidence indicates that teachers' stress and burnout impedes the development of positive teacher-student relationships, effective classroom management, and student well-being (Jennings and Greenberg, 2009; Roeser et al., 2013; Schonert-Reichl, 2017).

In the context of education, teachers can experience stress when they appraise a situation as threatening and yet have limited ability to change or improve it. Take, for instance, the case of teacher autonomy. Among professional occupations, teachers rate lowest in feeling that they have a say in what happens in the workplace (Gallup, 2014). The percentage of teachers who report low job autonomy increased from 18% in 2004 to 26% in 2012 (Sparks and Malkus, 2015). The proportion of teachers who report significant levels of on-the-job stress is also rising. In a recent Gallup (2014) on occupational stress, 46% of teachers reported high daily stress—on par with nurses and just above doctors. Teachers and nurses had the highest levels of reported stress among all occupational groups.

Why does teacher stress matter for our understanding of SEL? High levels of chronic stress can lead to occupational burnout—characterized by emotional exhaustion, depersonalization and a low sense of accomplishment in one's work (Maslach et al., 2001). Teacher stress has also been linked to decreased job satisfaction, poor instructional practices and poor student outcomes (e.g., Schwarzer and Hallum, 2008). Taken together, there is evidence that the occupational stress of teachers can thwart efforts to promote students' social-emotional competence and well-being.

Chronic work stress and exhaustion among teachers is also associated with negative changes in biological indicators of stress. Recent research has found that teachers who report chronic stress demonstrate atypical patterns of physiological stress reactivity, as assessed via daytime levels of the stress hormone cortisol (Katz et al., 2016; Wolfram et al., 2013).

Moreover, research also shows that, like other emotions, stress is contagious and can spill over into the classroom. That is, when teachers are stressed, students are the collateral damage. Drawing from the stress-contagion framework, Oberle and Schonert-Reichl (2016) examined the link between teacher burnout and student stress in a sample of fourth and seventh grade children in Canada. To assess teacher burnout, teachers completed the Maslach Burnout Inventory modified for Teachers (Maslach et al., 1996). To assess student stress, students' salivary cortisol was collected as a biological indicator of students' stress reactivity. Biological stress reactivity is frequently assessed via the reactivity of the hypothalamic-pituitary-adrenal (HPA) axis, a homeostatic system that follows a circadian rhythm and is activated in response to cognitive (e.g., fear, excitement, anxiety) or non-cognitive (e.g., infections) stressors (Jessop and Turner-Cobb, 2008). Cortisol levels found in saliva or blood can be used as an indicator for HPA axis activity. The integrity of the HPA axis is essential to human health. In a typical diurnal HPA-axis regulation pattern, cortisol levels rise within 20–45 min after waking and then gradually decline across the day. Inappropriately low or elevated levels of cortisol can compromise HPA axis functioning (Jessop and Turner-Cobb, 2008). Students' salivary cortisol was collected from children at 9 a.m., 11.30 a.m., and 2 p.m. in the classroom setting. Analyses revealed that, after adjusting for differences in cortisol levels due to age, gender and time of waking, higher morning cortisol levels in students could be significantly predicted from higher levels of self-reported burnout of classroom teachers. Although these findings were correlational, the research conducted by Oberle and Schonert-Reichl (2016) was the first to show that teachers' occupational stress is linked to students' physiological stress regulation. What is not yet known is the direction of the stress contagion. That is, does teachers' burnout lead to higher levels of stress in students? Or do students who enter the classroom with higher levels of stress lead to increased teacher burnout? Only future research determining this causal relationship will lend further clarity to this relation.

Promoting teachers' social and emotional competence and well-being

As can be surmised, the majority of extant studies have focused on teacher well-being through a deficit lens by examining the teacher stress and burnout (Spilt et al., 2011; Collie et al., 2015). This research has been in concert in showing a general lack of teacher well-being among teachers across the globe (Kyriacou, 2011). Moreover, the research has shown that higher levels of teacher stress and burnout is associated with concomitant levels of student problem behavior (Hoglund et al., 2015) and lower student academic achievement (e.g., Herman et al., 2018). Although these findings are valuable, one criticism of examining teacher well-being through a deficit lens is that it fails to identify the influential factors within a school system that serve to strengthen teacher well-being (Collie et al., 2015).

Reviewing the evidence linking teachers own SEL competence and student outcomes, Jennings and Greenberg (2009) point to the importance of quality teacher–student relationships, and effective student and classroom management skills, (as well as implementation dosage and fidelity) in obtaining the best outcomes for students. Accordingly, they recommend the development and implementation of interventions designed to specifically address teachers' SEL competencies, reduce teacher stress and burnout, and improve teacher well-being. Although limited, the past few years have seen the emergence of interventions specifically targeted at improving teachers' SEL and stress management. For example, two programs designed to promote teachers' SEL competence by incorporating mindfulness-based approaches are CARE (Cultivating Awareness and Resilience in Education) and SMART-in-Education (Stress Management and Resiliency Training). Mindfulness is typically described as an attentive, nonjudgmental, and receptive awareness of present moment experience in terms of feelings, images, thoughts, and sensations/perceptions (e.g., Kabat-Zinn, 1990). Both programs aim to increase teachers' 'mindfulness, job satisfaction, compassion and empathy for students, efficacy for regulating emotions, and decrease stress and burnout. Initial research to date has supported the effectiveness of both the CARE (Cocchia and Greenberg, in press; Jennings et al., 2011) and SMART-in-Education (e.g., Benn et al., 2012; Roeser et al., 2013) programs in promoting teacher SEL competence and well-being. Nonetheless, further research is needed to examine whether such positive changes in teacher well-being spill over into the classroom and lead to improvements in students' SEL competence.

Future SEL efforts on the horizon

Now more than ever, SEL is needed to revolutionize and transform education across the globe in order to enable all children and youth to thrive. Today, SEL is no longer seen as an ancillary aspect of classrooms and schools—it is seen as an essential component. Simply stated, "SEL is not another thing on the plate, it is the plate."

Although much has been learned in the past decade about SEL and its effects on children's social-emotional competence and academic success, the field has further to go before firm conclusions can be made about the specific ways in which an SEL approach advances children's short-term and long-term school and life success. Indeed, many questions still remain regarding the ways in which programs and practices designed to promote children's SEL skills will best support children's future success. Many questions remain, such as: How does a systemic approach to SEL lead to successful improvements in children's social and emotional competence and short-term and long-term success? Which programs work best for which children and youth? What does a transformative approach to SEL look like at all levels of the system? What are the policies that need to support effective SEL implementation at federal and state levels? and how do we adequately prepare and support teachers and principals to implement SEL in classrooms and schools?

Another challenge that confronts the field of SEL is the translation of knowledge garnered from rigorous research on the effectiveness of programs into policy and widespread practice across countries (Greenberg, 2010; Shonkoff and Bales, 2011). Clearly, there is a need for greater efforts to translate science for practice and policy so that SEL approaches can be better integrated into schools and communities. Such efforts can help build the processes and structures needed to foster high-quality implementation and promote sustainability (see Elias et al., 2003).

Finally, greater collaboration between researchers and educators is needed to allow research to not only inform practice, but also that practice can inform research. To create a world characterized by the values and practices that illustrate caring and kindness among all people, it is essential that educators, parents, community members, and policy makers work in concert to achieve long-term change. It is therefore critical that we make intentional efforts to devise the most effective educational practices that promote SEL in all children. Such efforts must be based on strong conceptual models and sound research. Only then will we be in a position to advance the development of our world's children and youth.

Acknowledgement

To the life and legacy of Roger P. Weissberg, for his leadership, collaboration, inspiration, and endless tenacity in advancing SEL research, practice, and policy to promote the well-being of millions of school children.

The fundamental processes that underlie learning can be seen as the processes that allow us to retain, update, and use information in new contexts. From a cognitive perspective, memory processes are essential components of learning that are constrained by attention and perception, and provide the basis for all higher-order cognitive functions as we recover and transform information to engage in acts of communication, comprehension, reasoning, and problem solving. In addition, learning can also be considered as the development or acquisition of skills, expertise, knowledge, or conceptual understanding.

Fueled by post World War II interests in advancing science and technology, the field of Artificial Intelligence flourished in the 1950s and 1960s and played a crucial role in the development of a cognitive approach to the understanding of thought that was built on an *information processing* framework (Broadbent, 1958). In this approach, the computer served as a powerful metaphor for the human mind. Broadbent is widely credited with developing the computer metaphor into an information processing model of human cognition with the guiding principles that the mind could be described in terms of input, internal representation or storage of information, processing, and output. Much of his work focused on exploring the limited capacity channels that constrain the input functions.

With the publication of *Cognitive Psychology* (1967), Neisser offered an initial definition of cognition as referring to all of the mental processes by which sensory input is transformed, reduced, elaborated, stored, recovered, and used. At the center of all these cognitive mental processes is memory. Memory is commonly thought of in terms of the processes that are responsible for acquiring information (*encoding*), retaining information (*storage*), and accessing stored information (*retrieval*). Just as memory serves as the fundamental basis for all cognitive processing, memory processes are also fundamental for learning. In many ways, all learning can be seen as the result of memory processes. All of the information and associations within our long-term memory store represent products of learning, and this memory store provides the basis for all other cognitive functions.

The goal for this chapter is to provide a broad overview of the fundamental cognitive processes involved in learning. Starting with early work using an information processing approach to explore different memory systems and processes, the chapter discusses

the critical constraints on learning that come from limitations in working memory capacity, as well as conditions that generally support better memory for information. In addition, a critical distinction is made between memory and comprehension outcomes, and an overview of conditions that support better understanding is provided. Learning is also considered as involving the development of skills, the acquisition of expertise, and engagement in knowledge revision or conceptual change. Finally, several other areas of research are highlighted that explore successful learning as part of a rich interplay between cognitive and metacognitive processes as well as those that allow the learner to pursue a deeper understanding of content including via interaction with others.

Memory processes

Given its prominence, a great deal of interest has been directed toward a better understanding of human memory. It is tempting to think of memory as simply a storage location that serves as the repository of all of our knowledge. However, information does not become a part of our memory via a singular path or process. Instead, there are a number of different types of processes associated with different memory functions. Although various taxonomic approaches have attempted to identify distinct types of memory stores and mechanisms (Atkinson and Shiffrin, 1968; Squire, 1987; Tulving, 1985), these are best seen as different perspectives on how we develop and use a rich, complicated interconnected network of associations. Nevertheless, it is helpful to consider some of these historical distinctions as they help to illustrate the factors that underlie learning and the many ways that learning can take place.

The modal model

Following from the information processing approach, one of the earliest models of memory was developed by Waugh and Norman (1965) and Atkinson and Shiffrin (1968), and is generally referred to as the *modal model*. The *modal model* of memory emphasized memory function in terms of how information is perceived and then moved into storage. The *modal model* attempted to capture the variability in the amount of time that information is available. It suggested distinctions among stores (or different *buffers*) that were defined by the duration that information is retained.

Sensory memory

An initial memory buffer, the *sensory memory store*, holds a large amount of incoming sensory information for only a few hundred milliseconds. This form of memory captures inputs in relatively unprocessed sensory form—iconic memory for visual inputs and echoic memory for auditory inputs. Although visual and auditory sensory memory have received the most research attention, there is thought to be a unique sensory store for each of the five senses. In general, any traces of sensory input that are represented in these stores are lost very quickly. Processes of selection and representation move information into the *short-term memory store*. Some of this information is then transferred into the much larger and more permanent *long-term memory store*. As information moves through these buffers or stages, perceptual and attentional processes serve as gatekeepers and determine what remains available for further cognitive processing.

Short-term memory

The *short-term memory store*, which receives input from sensory memory, holds by recent estimates only about four independent units of information for a few seconds (Cowan, 2014). Initial estimates based on Miller (1956) were that the capacity of this buffer might be closer to 7 units, plus or minus 2. But updated research and theorizing has suggested these were over-estimates that included some information that could be “chunked” or formed into meaningful units. In order for information to be maintained in short-term memory, it needs to be rehearsed, or it too will quickly be lost. Some of this information is then transferred into *long-term memory*. In contrast to sensory or short-term memory, long-term memory is characterized not just by its longer duration but also by its vast capacity. Yet, the ability to retrieve information at a later time depends on many factors, including how it is processed during encoding.

Immediate memory and working memory capacity

Modern approaches have advanced beyond the early *modal model* especially with respect to the notion of the short-term memory store. Current theories now tend to emphasize that short-term memory is not a storage place, buffer, or staging area outside of the long-term memory store, as much as it may represent information that is immediately available, currently active, currently being thought about, or information that one is currently processing or working on.

Baddeley's (2000) model of working memory characterizes *immediate memory* as a function of three distinct short-term memory subsystems, commanded by a *central executive*. One subsystem processes and stores visuospatial information, a second deals with phonological information (including speech), and a third integrates information from different modalities and temporal information into an episodic representation. Many studies using dual-task approaches have shown that sometimes we can do two tasks at once without a decrement in performance or without involving the central executive, specifically if a secondary task uses a different

subsystem than a primary task (Baddeley and Hitch, 1974). In contrast, sometimes attempting to do two tasks at once can cause performance to suffer, require involvement of the central executive, and put a *load* on working memory. Yet, other studies suggest that some single tasks may be so demanding that they load the central executive even without a secondary task.

An alternative approach characterizes *working memory capacity* from the perspective of individual differences in the general ability to control one's attention, or the ability to focus on a goal in the face of interference (Engle, 2002). This research has traditionally found that individual differences in attentional control affect the amount of information that people can consider in immediate memory, which in turn impacts their performance on many cognitive tasks. Regardless of whether a short-term or working memory approach is used to describe immediate memory, it is clear that there are severe processing limitations that exist. The ability to hold information in the focus of attention (or keep it active in working memory) is an important bottleneck that constrains human processing capacity (Cowan, 2014). These individual differences in capacity are generally found to influence how effectively or efficiently information may be encoded in long-term memory, and therefore often serve as strong predictors of learning outcomes and the ability to use information at a later time.

Long-term memory

Beyond the attentional bottleneck which constrains *whether* information may be encoded, the ability to use information at a later time also depends on *how* it was encoded. Thus, one set of distinctions among memory processes considers the way in which learning occurs. One main contrast is whether an individual intentionally attempts to learn information (*intentional learning*) or if the learning happens more incidentally by exposure (*incidental learning*, Postman, 1964). Learning can occur without explicit attention, as individuals are sensitive to patterns in their environments and can learn them implicitly (*implicit learning*, *statistical learning*). In contrast, when students are tasked with specific learning goals and they engage in an explicit attempt to memorize or learn information, this can be seen as intentional learning.

Other distinctions in long-term memory have been proposed according to content. Squire (1987) proposed a distinction between declarative and non-declarative memories, with *declarative memory* representing information that could be consciously accessed and declared (verbalized or stated), whereas non-declarative memory was comprised of non-conscious memories that are expressed through performance, such as *procedural memory* for actions or skills. A contrast that is typically used to illustrate this distinction is the difference between knowing the name of an object versus how you use it (what a bicycle is versus how to ride it). Similarly, in terms of language learning, vocabulary knowledge is often seen as declarative, whereas syntax is often seen as based in procedural memory.

Another common distinction that has been made is between episodic and semantic memory (Tulving, 1985). *Episodic memory* is thought to capture information from specific moments in time (autobiographical memory, memory for a specific event or episode). In contrast, *semantic memory* captures specific as well as abstracted, generalized concepts. Whereas episodic memory may be indexed by temporal context, semantic memory is thought of as a network of associations based in meaning. These different processes govern what information is encoded, how information is encoded, and whether and how information can be retrieved from long-term memory for use in higher-order processes such as communication, comprehension, reasoning, and problem solving.

Conditions that improve memory

Although all learners experience a bottleneck from the limited capacity of immediate memory, there are a variety of contexts or conditions that increase the likelihood that information will be remembered. These largely depend on two main mechanisms: repetition and meaningful associations. Engaging in practice for new associations, and integrating new associations with prior knowledge, are two ways that individuals can circumvent the limitations of the attentional bottleneck. Our ability to process information benefits from experience. Learners benefit from repetition, practice, and the automaticity that results from repeated experience with stimuli. Learners can also benefit from expectations based in prior knowledge and associations from long-term memory.

Practice effects in memory and skill acquisition

The extent to which information must be practiced, whether it must be explicitly processed, and how often information needs to be attended to during learning are important and well-studied topics (Pashler, 1998). Repeated exposure to information is one route to improving its likelihood of retrieval. Early in acquisition, novel skills or stimuli demand a great deal of attention. With repeated practice, processing becomes more automatic and requires less effort. Repetition benefits are often seen as *priming effects* (the amount of time it takes to recognize a stimulus decreases with repeated exposure). Benefits are also seen as *savings* during relearning attempts (it takes less time to re-learn the same list of words). Another typical finding is that the benefits from practice follow a *learning curve* with rapid improvement after initial practice followed by ever lesser improvements with further practice. Such negatively accelerated learning curves generally mimic power functions, thus, learning is often said to follow the *power law of practice*. This is typically the trajectory that is followed during skill acquisition (like learning motor sequences or procedures) as skills become more automated or proceduralized. Some examples of the benefits that are seen due to practice or repeated exposure include faster reading times for more common words (*word frequency effects*) and faster computation times for single digit number facts (e.g., $2 + 3$).

Skill acquisition in language, reading, and math

The fundamental processes involved in learning in several domains can also be considered from the perspective of developing skills over time. First-language acquisition is perhaps the most impressive of all cognitive feats. Language develops universally in some form in all humans, and development typically proceeds in a remarkably rapid fashion. Modern approaches emphasize both the biological predisposition to acquire language as well as the role of exposure to patterns in the environment (Gleitman and Newport, 1995). In contrast to first language acquisition, adult second language (L2) acquisition occurs under more variable learning conditions. Second language acquisition is typically assumed to occur in a more explicit, intentional, or strategic fashion than first language acquisition. Whereas most adults acquire their L2 at least partially through explicit instruction, as in a classroom setting, many others acquire their L2 primarily through implicit exposure, as is typical of an immersion environment. Although it has been widely believed that adults cannot learn a second language in the same way that children learn a first language, recent evidence suggests that adult learners of a second language can sometimes be indistinguishable from native speakers, and that this may be more likely under implicit learning conditions and with high quality input (VanPatten et al., 2019).

A great deal of cognitive research has also explored the development of reading skills. This research supports two important conclusions: first, that mastering the alphabetic principle (the idea that written symbols correspond to sounds, or phonics) is essential to becoming proficient, and second, that methods that teach the alphabetic decoding principles are more effective than methods that do not, especially for children who are having difficulty learning to read (Rayner et al., 2001).

Just as humans are thought to be predisposed to learn language, mathematical understanding is now thought to develop from an intuitive approximate number system. Beginning in early infancy, the approximate number system tracks differences in magnitude. It is thought to play a crucial role in development of other numerical abilities, such as the concept of exact number and simple arithmetic (Feigenson et al., 2004).

Testing effects

Just as repeated practice increases the ability to perform a skill well, repeatedly retrieving information stored in memory strengthens the memory trace and increases the likelihood that it can be retrieved again at a later instance. This phenomenon is known as the *testing effect* or *retrieval practice effect* (Roediger and Karpicke, 2006). Moreover, repeated retrieval also affects subsequent memory for associated information. Memory is reconstructive, and every time a memory is retrieved, it is altered. What information is tested may affect what is retained. Retrieving some information from memory can cause other non-retrieved information to be forgotten, known as *retrieval-induced forgetting*. Also, although retrieval practice can strengthen memory for retrieved information, it can increase false memories and cause other memory errors. For example, when distractors are presented as part of multiple-choice practice test questions, they can lead to memory for the incorrect answers.

Spaced practice effects

The benefits that come from practice become larger when it is spaced and repeated over time (Cepeda et al., 2006). Spaced practice schedules that involve either distributed or interleaved practice have been shown to lead to more robust learning than massed or blocked practice. *Distributed practice* occurs when students engage in repeated practice spaced out over time as opposed to practice being massed within a single session. *Interleaved practice* occurs when practice alternates between two or more concepts (such as subtraction and addition) as opposed to the two concepts being practiced separately. Practicing more than one concept at a time allows for comparisons to be made between the concepts, while spacing allows for some forgetting to occur between attempts. This means that to recover the information will require a more effortful retrieval process. The additional effort that is required ultimately strengthens the accessibility of the information in memory (Bjork, 1994). Another advantage from spaced learning is that the passage of time also changes the context of learning. With exposure to information in different contexts, the information becomes much more likely to be accessible in different situations and with different cues in the future.

Generation effects

When learners are asked to construct a response during learning, this has been shown to aid memory. In one classic demonstration of the *generation effect*, Slamenka and Graf (1978) found that words that are generated by learners are remembered better than when those same words are simply read. They showed this by asking learners to generate target words using a rule (opposite, synonym, or category member) from a cue word and a first letter (e.g., opposite: long—s _ _ _). Generation led to better memory for the generated response (short) than if the same words were presented to be read (long—short). In another demonstration, Jacoby (1978) showed that when learners were prompted to “solve” word fragment problems with associate words (e.g., foot—s _ _ e) they had better memory for the solution word (shoe) than when learners were simply shown the intact words (foot—shoe). One explanation for these benefits is that generating or constructing a response prompts the learner to take a more active role in the learning process, as opposed to passively receiving information. As with the benefits seen due to spaced practice, this greater effort during encoding leads to an increased chance of retrieval in the future.

Semantic processing effects

A long tradition of research has demonstrated more durable learning and memory from contexts that allow for the learner to generate meaningful connections or associations—when information is presented in a context that allows for elaboration or integration with prior knowledge. One of the seminal studies showing these effects is [Craik and Lockhart's \(1972\)](#) experiment on *levels of processing*. Individuals can process information on a number of different levels. When readers were exposed to word lists and asked to consider surface-level details such as whether the target words were written in capital letters (CHAIR), they found that memory was generally worse than when they were asked to consider the sound of the target words (e.g., Does this word rhyme with FLARE?). Further, people were best able to recall target words when they were prompted to consider their meaning during exposure (e.g., Is this a piece of FURNITURE?). Because the learner could integrate the target words more deeply into their long-term memory when they were prompted to consider the meaning of the words, this benefit is referred to as the *depth of processing effect*. Processing information in terms of its meaning leads to more associations, more integration with prior knowledge, and more elaborated memory traces. This helps the learner to leverage their prior knowledge when learning, to resist interference from competing pieces of information, and to have a richer set of retrieval cues which increases the chance of having access to the information in the future.

For similar reasons, new information is generally better recognized and recalled when it is supported by a meaningful context. For example, the *word superiority effect* results in individual letters being recognized more quickly when they appear in words as opposed to non-words ([Cattell, 1886](#)). Additionally, words are recognized more quickly when they appear in meaningful sentences ([Stanovich and West, 1979](#)). Similarly, experts have better memory for information that can be directly related to their domain knowledge. For example, chess experts are able to use their extensive knowledge of chess to remember the locations of pieces on a chess board that they are shown only very briefly ([Chase and Simon, 1973](#)). And, baseball fans have better memory for baseball games ([Chiesi et al., 1979](#)). Experts' prior knowledge is a richly connected network of associations, which provides a structure that allows them to easily encode and retrieve relevant information.

Text is also more memorable when it fits expectations and can be integrated into our prior knowledge. Individuals use their generic knowledge of typical event sequences and about everyday things (*schemas*) as an organizing framework for their memory. When we are given a context that allows us to use our prior knowledge, then our memory is greatly supported. There is a substantial body of work that shows how schemas can affect our memory. Sentences such as "First you arrange things into different groups. Of course, one pile may be sufficient depending on how much there is to do." are much easier to recall if you know they are about "Washing Clothes" ([Bransford and Johnson, 1972](#)).

In general, memory tends to be more robust as the learner engages more meaningfully or actively with information during encoding. Integrating the new information with prior knowledge, developing a richer memory trace with elaboration, or strengthening a memory trace through spaced or interleaved practice, are all conditions that generally will help improve the likelihood that information will be learned, remembered, and available in the future.

Comprehension processes

Although accumulating information in long-term memory is one goal of learning, another goal is for students to comprehend and understand new concepts. In contrast to simple retention of information, which can be strengthened through practice, comprehension requires processing information in terms of its meaning ([Kintsch, 1994](#)). The most common methods used to convey subject-matter understanding are reading expository text or listening to lectures. In these cases, learning depends on the comprehension of text or discourse. Theories of text and discourse processing propose that multiple levels of representation may be constructed from this information. For example, according to Kintsch's framework for comprehension based in the Construction-Integration model ([1998](#)), at the most basic level (the *surface level*) the learner forms a representation based on the exact words that they read. Beyond that, the learner may represent the meaning of each point made by the text in a slightly more abstracted, propositional, or gist form. This level of representation is known as the *textbase*, and still closely follows the information presented in the text. In contrast, as a learner attempts to understand what a text is about, it requires them to connect ideas across different parts of the text, and to integrate new information with relevant prior knowledge from long-term memory, to make inferences and generate relations that are only implied by the text. It is constructing this deeper level of representation, generally referred to as a *situation model* or mental model, that represents understanding or comprehension, and allows students to apply or transfer their knowledge to new situations ([Mayer, 1989](#)).

Conditions that improve comprehension

Because of the important role that integration with prior knowledge plays in the comprehension process, the benefits that come from possessing relevant general knowledge or expertise in a domain also extend to comprehension outcomes ([Bisanz and Voss, 1981](#)). Schematic processing which can be prompted by even just providing a title for a passage improves not only memory for

the content but also the ability to comprehend or understand it (Anderson, 1978). In addition, comprehension processes can be supported by a variety of instructional conditions that may help students with low prior knowledge also develop understanding. These instructional conditions help to encourage students to engage in the reasoning processes that are required to construct a situation or mental model of the content.

Goal-directed or purposeful reading

The processes that students engage in while learning depend on their perception of the goal or purpose for the activity, and it is important for students to be provided with specific goals or instructions prior to reading (Britt et al., 2017). These goals may direct the reader's attention to specific concepts in the text, serve as test-expectancies, or provide guidance about what might be needed for other post-reading tasks that may alter behaviors during reading. By clarifying the purpose for reading, it not only makes the task more meaningful, it also allows learners to make better decisions about how they are reading, and to better monitor whether they need to exert more effort to comprehend the information for a future application or examination.

Learning from questions and explanations

Activities such as elaborative interrogation or responding to adjunct questions can support construction of better situation models during learning. Generating questions and explanations can also encourage the activation and use of prior knowledge, and can aid monitoring of understanding and where gaps may exist in understanding (Graesser and Person, 1994). Although these activities can be effective for improving comprehension, the effects are highly dependent on the level of processing that the learner engages in during the task. To be most effective, the learner should be focused on constructive processing in which they are actively generating new inferences left implicit in the text as opposed to solely retrieving information already explicitly available in the text (Hinze et al., 2013).

Learning from multiple sources

With the emergence of the Internet, students are increasingly being tasked with learning from multiple sources, such as those obtained from web searches. Engaging in inquiry with multiple sources is a complex activity because it requires all the processes necessary for learning from individual texts, plus an additional set of processes that become particularly important when readers are confronted with information from more than one source (Wiley et al., 2018). Comprehending events or phenomena from multiple sources instead of a single source necessitates representation of information about the origin, nature, or quality of the various sources (who wrote it, for what purpose was it written, is it reliable), as well as relations between the sources (the presence of corroborating or conflicting statements, detecting consistency or inconsistency). With a single source, the construction of a good-enough situation model can often be achieved by representing the original text's intended purpose, structure, or argument in memory. However, when tasked with comprehending an event or phenomenon from multiple sources, the learner must actively impose selection, organization, and transformation to construct a mental model that integrates the information from different texts, rather than more passively creating distinct traces for each individual text. This provides an opportunity for richer student understanding. Learners may benefit from learning from multiple sources to the extent that they actively engage in constructive processing, attempt to build connections across ideas, and try to form a coherent, integrated model of the phenomena. Although different reading goals may affect learning in single-source contexts, they become even more critical to consider in multiple-source contexts. The likelihood of engaging in these activities depends on the learner's interpretation of the task, as well as individual differences such as epistemic or epistemological beliefs.

Learning from multiple representations

Exposure to multiple representations can also support better learning. When attempting to learn a new construct, adding alternative representations such as diagrams can provide other routes to understanding (Ainsworth, 2006). For example, while generating written explanations can support understanding, sketching can be thought of as a visual explanation process that can also support understanding.

Alternatively, gestures can be used to support spatial thinking, but also may be used to represent or express knowledge that is difficult to verbalize (Alibali, 2005). Gestures may reveal a student's preparedness for learning a concept even when their verbal expressions suggest poor understanding. Interestingly, although we may think of gestures as devices used to communicate with others, gestures can also be useful for helping students to clarify their own understanding.

Presenting multiple cases or adding an analogy can also provide a basis for understanding, allowing learners to compare or map relations across different contexts, and abstract important information (Catrambone and Holyoak, 1989). Research has also shown that presenting alternative representations or contrasting cases to the learner in a way that supports comparison and identification of distinguishing features can help the learner to form generalizations, and prepare the learner for future learning.

Conceptual change and restructuring processes

Although learning can sometimes proceed by simply adding to existing knowledge, there are times when learners need to overcome some of their intuitive ideas in order to comprehend accurate concepts of phenomena. Following [Piaget \(1977\)](#), learning can be characterized as resulting from two fundamental processes: adaptation and disequilibrium. *Adaptation* involves using existing knowledge as a basis for understanding new information by either assimilation or accommodation. *Assimilation* is the direct application of previously known concepts to the novel stimuli. *Accommodation* is the updating or fine-tuning of previously known concepts in the face of new information. Prior knowledge is refined by this process. *Disequilibrium* occurs when the new information cannot be simply added to or easily accommodated by previous concepts. In these cases, when new information or evidence in some way conflicts with prior understandings, then restructuring, *conceptual change*, or belief change is required ([Chinn and Brewer, 1993](#)).

Some of the most prominent ways to help students to engage in radical conceptual change or restructuring processes attempt to put them in situations where they must directly confront the inconsistency or conflict caused by the incorrect conception ([Vosniadou, 2013](#)). Some instructional contexts introduce anomalous evidence. Other instructional contexts employ refutational texts where an intuitive or incorrect conception is explicitly flagged and contrasted with the preferred conception ([Hynd and Alvermann, 1986](#)). Importantly, in order for conceptual change to occur, not only must some conflict or inconsistency exist and be noticed, but the learner also needs to actively engage in resolving it ([Diakidoy and Kendeou, 2001](#); [Limón, 2001](#)).

The process of constructing a correct representation is important not just for developing understanding when learning from text, it is also important for successful problem solving ([Koedinger and Nathan, 2004](#)). The first stage of the problem-solving process requires the construction of a problem representation, which is followed by the subsequent solution stage. When learners initially choose an incorrect problem representation, then they need to engage in representational change and restructure their interpretation of the problem in order to make progress. Starting with an incorrect representation is a common issue that arises for a number of reasons including misinterpreting linguistic expressions in word problems, misunderstanding of symbols, or depending on inappropriate concepts or prior knowledge (such as attempting to use arithmetic rather than algebraic approaches). In these cases, it is often useful for learners to reach an impasse or experience failure, as this can prompt reflection and revision as part of the representational change process.

In general, comprehension requires that the learner engages meaningfully and actively with information to construct a representation of what they are learning about. Integrating new information with prior knowledge, making connections across sentences or sources, mapping across information formats, detecting inconsistencies or conflicts and taking action to resolve them, all support better conceptual understanding and more coherent mental models.

Other conditions that improve learning

This final section highlights several areas of research that build on the key observations that successful learning depends on students engaging in meaningful, constructive, and reflective processing: the role of interaction with others; the role of an initial invention, exploration, or discovery phase on preparation for future learning; the role of feedback; and the role of monitoring in effective self-regulated learning.

Active and interactive learning with others

In contrast to the adaptation and restructuring processes that were emphasized as fundamental to learning by [Piaget \(1977\)](#), [Vygotsky and Cole \(1978\)](#) emphasized the processes of learning that come from interactions with others, and in particular from a more knowledgeable other. A common theme in educational research is exploring the ways that social interaction can support learning through small-group exercises or peer collaboration activities such as *reciprocal teaching* ([Palincsar and Brown, 1984](#)) or *learning by teaching* ([Guerrero and Wiley, 2021](#)).

[Chi's \(2009\)](#) ICAP (Interactive, Constructive, Active, Passive) framework places interactive processes as more effective than other constructive or active learning processes, which in turn are more effective than passive learning processes. Interacting with peers during learning can provide all members of a group with relevant knowledge that only few students may possess. Each member can contribute a new perspective or specific skills. Working with others can help to support planning and execution of complex tasks. Others can also provide feedback. Students can support each other by prompting evaluation, explanation, abstraction or reflection.

Learning by invention, learning from errors, preparation for future learning

Several lines of research have explored how the sequencing of learning activities influences the knowledge that learners construct, and their ability to use it in new contexts. Although many traditional approaches expose students to content via a reading or a lecture before they engage in quizzing or problem-solving activities, some alternative approaches have students engage in carefully designed inquiry, exploratory, or discovery activities before receiving direct instruction (*preparation for future learning*, [Schwartz and Martin, 2004](#); *learning by invention*, [Jarosz et al., 2017](#); *productive failure*, [Sinha and Kapur, 2021](#)). In an example

of a learning-by-invention paradigm, students work together in small groups to try to develop a method of quantifying variability before they engage in a follow-up discussion with the teacher in which they are taught the canonical formula for standard deviation. Although student groups are rarely successful at inventing the canonical formula on their own during the invention phase, the initial activity leads them to failures or impasses. The difficulties they experience during these attempts can help them to recognize gaps in their knowledge, which then greatly enhances the uptake of the subsequent lesson. In other words, by putting exploration and active learning first, these activities prepare students for future learning. Ultimately this helps the lesson to become much more meaningful, and students are much better prepared to transfer and use the information in new contexts (Schwartz and Bransford, 1998).

Importance of feedback and guidance

Opportunities that come from practice testing, initial exploration activities, or activities that involve interacting with peers also mean that students may be exposed to incorrect ideas. Feedback can play an important role in the active learning process by helping students to correct errors that may be generated. Feedback not only helps to direct attention toward correct information, and prompts students to repair and update incorrect representations, it provides guidance for future learning, and can help to lower cognitive load during learning (Shute, 2008).

Interacting with others can be particularly motivating, but there are also a number of pitfalls that can make collaborative learning less successful than individual work. Guidance for students on how to collaborate is critical, otherwise they may engage in superficial discussions that do not reach a high level of discourse. Invention activities are also highly motivating, but the guided discussions or reflection activities that follow exploratory or generative activities are critical to leverage the advantages of learning from invention, errors or failures. Intelligent tutors can guide students with an interactive experience that can offer timely feedback and expert knowledge (van Lehn, 2011). But if systems provide too much scaffolding or help, then the students may never actually meaningfully engage with the content.

Metacognitive monitoring and self-regulated learning

Metacognition is the act of monitoring one's own cognitive processes and includes assessing one's own learning, memory, and understanding (Brown, 1978; Flavell, 1979). These monitoring assessments then serve as input to the self-regulated learning process (Winne and Hadwin, 1998), and to the decision making that the learner engages in when choosing among behaviors and actions that can be taken. Accurate monitoring allows learners to make better decisions and engage in more effective self-regulated learning.

Much research on the topic of monitoring accuracy has used prediction paradigms for memory and comprehension tasks. *Metamemory* paradigms typically consist of tasks that include learning word pairs, such as a word in a foreign language and its English translation, or definitions for new vocabulary (Dunlosky and Metcalfe, 2008). When learners are asked to predict their ability to recall a translation or definition, metamemory accuracy has been found to be quite good, especially when judgments are made at a delay. When learners are asked to predict how well they will do on a test of comprehension following the reading of expository texts, *metacomprehension* accuracy is typically much lower. Yet, several contexts have now been found to promote accurate metacomprehension (Griffin et al., 2019). When learners are given clear comprehension goals as their purpose for reading, or are prompted to self-explain during learning, metacomprehension accuracy can be substantially improved. The ultimate value of supporting better monitoring accuracy among learners is that it then can help them to make effective decisions of what to re-study as they attempt to master material on their own.

Conclusion

This overview began with the consideration that memory is at the center of the fundamental cognitive processes that underlie learning. Much work has shown that human memory takes a variety of forms and may contribute to learning in different ways. Our ability to learn is affected by the attentional bottleneck which constrains our immediate capacity. Our learning can be improved by engaging in practice, repetition, and making meaningful associations based in memory. Comprehension fundamentally depends on memory, but in addition requires the learner to engage actively with the information to develop a more conceptual, complex mental representation. Many contexts that have been demonstrated to support effective learning outcomes involve engaging students in constructive, interactive, and reflective processes. Moving beyond these fundamental cognitive processes, broader approaches consider the rich interplay between cognition and metacognition for successful learning, as well as the critical role of motivation, curiosity, interest, and willingness to invest in learning and to explore what one does not know.

Some excellent overviews of how research on fundamental cognitive principles of learning can be applied to instruction and educational contexts can be found in Dunlosky et al. (2013), Roediger and Pyc (2012) and the *How People Learn* series (National Academies of Sciences, Engineering, and Medicine, 2018).

The connections between the nodes of attention networks develops slowly over childhood and is influenced by the interaction of genes and the parental environment. The development of attention networks supports both self-regulation and the child's understanding of other minds.

Posner et al. (2020, p 220).

A child's ability to direct his or her attention drives awareness; only objects and events attended to will enter the child's mind. In this sense, attention processes are essential for learning and cognitive development. Attention influences and is, in turn, influenced by various brain systems, an interaction that creates priorities affecting both perception and action. Thus, alertness and the way attention regulates, or is regulated by, brain functions becomes highly relevant for all domains of learning. Without attention it becomes difficult, if not impossible, to take in new and important information. We, adults and children, are active in selecting what to attend to and what to ignore – a process that becomes more and more voluntary during development.

Attention in infancy

The view of an infant during the first months of life as passive, incapable of communicating and remembering, and unaware about self and others has changed radically during the last 50–60 years. Typically, developing infants have a sensory system, which makes them capable of perceiving and interacting with the environment promoting communication, emotional exchange, and signals for caretaking. In addition, they use their own body as a vehicle, not only for exploration of themselves, that is, building sensory motor schemas, but also for assembling information about other individuals. To learn from and understand other people and socially relate to them is crucial for a healthy development. In short, newborn children enter this world equipped with a couple of biases that helps them to initiate and maintain attention to other people (Bjorklund, 2021). Among those biases are (1) a probably innate ability to attend to biological motion; (2) an attractiveness to faces or face-like patterns; (3) a tendency to direct more attention to human speech sounds than other sounds in the immediate environment; and (4) an ability to respond in an imitative-like fashion already at birth.

Furthermore, by 4 months infants look longer if there is a mutual eye gaze with the adult compared to averted eye gaze. Also, auditory perception in 6-month-old infants is linked to sensitive detection of human voices, such as discrimination of phoneme segments, both in native and foreign languages. However, during the second half of the first year of life this ability declines showing

that early on our brain is prepared for a general language acquisition, but that exposure to one language with its specific prosodic and phonetic patterns reduces this capacity.

All sensory systems are functional at or before birth and of these, the visual system is probably both the best-understood and least-mature system. It is actually a difficult task for the newborn infant to respond to visual stimuli. When a newborn infant acts on complex visual information, as evident when the neonate mirrors facial movements, the infant responds in spite of the immaturity of the visual system: Jerky eye movements make it hard to control vision and it is difficult for the immature system to capture fast-moving objects. In short, the infant's control of fixation is mostly not under voluntary control at birth and, during the first months of life, infants cannot resist being drawn to certain patterns. Visually, the newborn infant is attracted to high spatial frequencies (e.g., checkerboard pattern and edges), to slowly moving objects (moving stimuli are more attractive than static ones), and to face-like patterns. The attraction to edges provides necessary input for the visual cortex to develop (input helps to organize cell columns in visual cortex) while the attraction to face-like patterns guides the infant toward the social world.

All nonvisual sensory systems are also functional at birth but their role in early attentional processes is less well studied, although auditory attention probably is as important as vision for early development. Hearing is essential both for language learning and for making the social world interesting. The newborn infant recognizes human voices at birth (in fact, a fetus can learn to identify the mother's voice several weeks post-partum) and the melody of the mother tongue is identified within the first weeks. The human voice, especially the female voice, attracts the infants' attention both to the social world and to language.

Selective attention

Selective attention develops rapidly over the first months of life. The newborn infant has less oculomotor control, less control over attentional shifts, and is attracted by salient details in perceptual displays. A neonate is not able to understand a partly occluded object as a unity and reacts only to direct visible information. It becomes a very difficult task if the neonate must identify a center-occluded object – the infant sees only the top and the bottom part of the object – in order to solve a task. This does not imply that a newborn child is not able to take in the relevant information, only that during the first months of life, perception and attention is more driven by environmental input (exogenous processes) coupled with biologically driven subcortical processes. Slowly, vision becomes more and more cortically controlled, acuity develops, the visual field increases, the eyes become better coordinated and inspection times decrease. A shift is usually seen around 2–3 months making the infant more visually competent when inspecting new objects, and, maybe most important, the child now becomes able to partake in prolonged face-to-face interactions with the caregiver.

The problem with perceptual completion, to see an object as a whole in spite of the fact that it is partly occluded, also changes during the first months of life. Some capacity is observable already at 2 months, but it is not until 4–5 months that the ability to solve perceptual-completion problems can be expected to be robust. Interestingly, children at 3 months seem to be in a transition phase. In an informative eye-tracking study, [Amos and Johnson \(2006\)](#) identified two groups of children, perceivers and non-perceivers: the children who were able to perceive unity (i.e., they solved the perception-completion task) used a more efficient strategy when solving a visual search task than the non-perceivers. These differences may stem from the possibility that the two groups reflect different stages in early brain development, the children are in the midst of a transition from exogenous to more endogenous oculomotor control, or, in the authors' own words, "...differences between groups of 3-month-olds on visual search performance may be related to different stages in the development of visual pathways underlying oculomotor control" ([Amos and Johnson, 2006](#), p. 1244). Selective attention is important since it makes it possible for the child to be an active participant in his/her development and early differences in this ability might have an impact on later cognitive development.

The capacity to attend selectively is also related to disengagement, an ability that develops rapidly over the first months of life. As depicted in [Fig. 1](#), infants younger than 2 months tend to focus on one stimulus at a time. If a second stimulus is added to the visual display while the first stimulus is still visible, the infant is more or less unable to make a gaze shift. However, by 3–4 months, this is no longer a problem.

Selective looking and habituation have dominated research on infant attention. Generally, the length of looking declines during infancy, especially from 3 to 4 months and onward. Younger infants need longer inspection time (familiarization) than older infants; studies indicate a negative correlation between visual recognition and the inspection time needed. Selective attention has also been used to study auditory attention (e.g., the ability to discriminate between specific sound signals or between the mother's voice and a stranger's voice).

Attention to faces

Human infants show a preference for faces right from birth, a tendency that seems to be especially strong for moving face-like stimuli ([Johnson et al., 2015](#)). This has been interpreted by some as indicating a pre-wired system molded by evolution. Such a system is described as being controlled by subcortical parts of the visual system functional at birth making the face a highly salient stimulus for the newborn. Evidence based on electrophysiological brain responses (ERP) show that cortical areas start to become more selectively attuned to faces around 3 months of age ([Conte et al., 2020](#)). Thus, the child is endowed with an in-built perceptual attention grabber for face-like patterns. Although the propensity for faces among newborns is not debated, the mechanism is. In a series of studies, Simion and co-workers ([Simion and Di Giorgio, 2015](#); [Buiatti et al., 2019](#)) have provided support for an alternative view. Instead of being born with a module sensitive specifically to faces, they argue that newborns are born with "pre-wired

Fig. 1 The ability to disengage and shift gaze was studied in 16 infants observed longitudinally from 6 to 26 weeks. Gaze shift is indicated by the infants' responses to competition trials which required disengagement from one stimulus before a second (new) stimulus could be attended to. In noncompetition trials, the infant always saw only one target at a time. As can be seen from the graph, early development is characterized by a high degree of discontinuity. A rapid change is noted for the period 8–14 weeks, whereafter change continues but at a much slower pace. From [Butcher, Kalverboer, and Geuze \(2000, p 11\)](#), reprinted with permission.

domain relevant attentional biases toward faces" ([Simion and Di Giorgio, 2015, p 7](#)). These biases include sensitivity to top-heavy patterns, congruency and configural properties of the stimuli—biases that have the effect that faces becomes salient for the newborn in spite of the fact that the system is not specific to faces. Specific face systems build up with time as the infant gains experience and the relevant brain systems matures (e.g., the fusiform face area and the superior temporal sulcus) and becomes better integrated. The observation that infants early in life prefer own-race faces is a further indication of how experience molds our face recognition system. The conflict between the two contrasting views presented here is not resolved; we still do not know exactly how to describe the mechanism responsible for making newborn babies especially attracted to the human face or how a mature system for face representation develops.

Furthermore, observations also suggest that infants are better at processing female than male faces, a finding that probably stems from the fact that infants have much more experience in processing female faces. In addition, a child's temperament might also influence how faces are processed. Temperament factors such as orienting and surgency have been shown to affect how 6–10-month-old infants view faces according to race and/or gender ([Rennels et al., 2020](#)). Finally, over the course of the first year, infants begin to process naturally looking faces in the same fashion as adults do; that is, they analyze faces in a holistic gestalt-like fashion. Whereas 4-month-old children focus more on internal facial features, 10-month-old children use a holistic strategy. Six-month-old children seem to be in a transition phase using both strategies.

Attention networks

Behavioral phases

Attention in infancy is usually described as made up of separate phases representing different underlying processes. Arousal, a prerequisite for attention, reflects the physiological readiness of the organism to react to any stimuli. Usually, arousal varies from deep sleep to active wakefulness through several intermediate phases. A characteristic of the young infant is that state changes occur often and rapidly, which affects the manner in which early attention is modulated. Without adequate arousal, the child will not be alerted to an endogenous or exogenous stimulus and no attention can take place ([Colombo and Salley, 2015](#)). Behaviorally the process of attending can be parsed into three distinct phases ([Colombo et al., 2001](#); see [Fig. 2](#)). The first phase is an initial brief *orienting* (OR, sometimes also called selective attention) when the infant's attention is directed toward specific stimuli; that is, an interesting event is identified, and the system becomes prepared for further inspection. The second phase is *sustained attention* (SA), which reflects a period of active information processing or encoding. SA is often described as a voluntary process and it has been linked to anterior brain systems. In the newborn child SA is mostly governed by parents working actively to keep the child's attention. The final phase, *attention termination* (AT), on the other hand, is linked to disengagement processes reflecting continuous looking after cessation of any active information processing. AT has been proposed to reflect the posterior brain system and the disengagement processes have been observed to be a stronger prediction of recognition than sustained attention, at least for static stimuli.

Fig. 2 The figure depicts how the three phases of attention described in the text might be observed when studying visual attention in infancy. In this particular study, 113 four-month-old infants participated; visual looking and heart rate (beats per minute) responses defined the phases: OR = Orienting; SA = Sustained attention; AT = Attention termination. Prestimulus baseline refers to baseline heart rate level. From Colombo et al. (2001, p. 1609), reprinted with permission.

Brain networks

In several studies, Posner and colleagues (e.g., Posner et al., 2013; Posner et al., 2020) have integrated behavioral and cognitive neuroscience studies in order to trace the development of attention from infancy to adulthood and to outline the three major brain-behavior networks (see Fig. 3) that underlie central aspects of attention: the alerting, orienting, and executive networks.

The first aspect, alerting, signifies that the child is in a state of readiness for reacting to new incoming stimuli. From a biological point of view, alerting has been linked to subcortical processes (locus coeruleus) as well as to right parietal and right frontal areas. Norepinephrine is the main neurochemical modulator.

Fig. 3 The figure shows the different nodes of activation for the three main attention networks: alerting, orienting, and executive attention networks. From Posner et al. (2013, p. 396), reprinted with permission.

Fig. 4 The graph illustrates hypothetically how the orienting and the executive networks influence the development of self-control over the first seven years of life. From Posner, Rothbart, Sheese, and Voelker (2014, p. 2), reproduced under the Creative Commons Attribution License.

The second aspect, orienting, means that attention aligns with incoming sensory signals and that some information is selected. It is activated by posterior parts of the brain, mostly the parietal lobe (e.g., the superior parietal lobe, the temporal parietal junction, and the intraparietal sulcus) but also some frontal (frontal eye fields) and subcortical areas (pulvinar and superior colliculus). It is commonly assumed today that these areas represent two different control systems in the brain. One dorsal attention system involved in top-down visuospatial processes and one more ventral attention system more involved in bottom-up processes important for reorienting (Petersen and Posner, 2012). The main neurochemical component for the orienting systems is acetylcholine. “For newborn infants, the control of orienting is initially largely in the hands of caregiver presentations” (Posner et al., 2013, p. 400). By four months the infant has gained substantial voluntary control over his/her orienting responses and by late infancy self-regulatory capacities start to develop. A hypothetical relationship of how attention influences the development of self-control over the first seven years of life is illustrated in Fig. 4.

The final aspect, executive attention, indicates the ability to monitor responses, thoughts, and feelings, a process that not only involves mainly anterior brain areas (prefrontal cortex and the anterior cingulate gyrus) but also parts of the basal ganglia (e.g., striatum). Biologically, two separate brain systems have been identified that together seem to control executive attention (Petersen and Posner, 2012), one important for the moment-to-moment task requirements (the frontoparietal system) and one that is central for sustained attention (the cingulo-opercular system). It is hypothesized that executive attention plays an important role in the ability of the developing self to regulate positive and negative affect. Dopamine is the main neurochemical modulator although serotonin is also involved.

The more posterior parts of the attentional system develop relatively early. Thus, the young infant is more able to alert and orient than to show executive attention, although it takes time for these systems to become fully mature as well. The first signs of the executive system can be noted toward the end of the first year (e.g., as in the A-not-B task), but it will take about 8–10 years for it to reach adult-like levels although response time measures indicate continuous improvement into late adolescence. An additional finding relevant for understanding development is that connections between brain areas change over time. The young brain relies more on short connections in comparison to adults who have networks that includes long connections. Brain systems become more separate and functionally focused during development.

All three networks – especially the executive network – are essential for the infant to develop an ability to display effortful control, that is, to self-regulate one’s own behavior. In fact, the high-level temperamental construct effortful control, has been used as a proxy in studies on executive function in infancy. Effortful control reflects how well a child can suppress a major impulse in order to act on a second, less strong impulse. Temperamentally, effortful control builds on measures of the ability to control impulses, to shift attention and to focus attention (Putnam et al., 2006).

Attention and developmental disorders

Problems with attention are probably of importance for various neuropsychiatric disorders (Posner et al., 2019). As an example, the hyperactivity and concentration difficulties observed in ADHD have been found to be associated with the alerting network while disengagement deficits often noted in autism has been associated with the orienting network. Finally, the executive network has been associated with recurrent thoughts and repetitive behaviors often problematic for people with OCD. It is however important to keep in mind that attention is only one of many aspects of a disorder and also that, within a disorder, the relevant attention network can change over time. It has, for instance, been suggested that for ADHD, problems with alerting are most evident early in life while problems with the executive attention network become prominent later. It is also likely that attention problems might be important for reading difficulties or reading processes. A recent study showed that fluent reading in 8–12-year-old children was associated with functional connectivity between the orienting and executive networks. High fluency and high connectivity were found to be significantly associated. This held for both typical readers and for children with reading difficulties (Freedman et al., 2020).

Genes and attention

The observation that each of the three networks are associated with different neuromodulators has made it possible to investigate possible genetic links underlying each network. Genes found to influence norepinephrine seems to influence primarily the alerting network but not orienting, whereas genes affecting the cholinergic modulator are important for the orienting network. For the executive network, genes linked to dopamine and serotonin have been identified. Although several genes have been linked to attention processes there is no one-to-one correspondence between genes and attention. The genetic influence is complex due to genetic polymorphism, epigenetic factors, and environmental influences. The environment seems also to exert a strong influence, especially early in the development, through parenting practices, especially for the development of the executive network as shown through the child's ability to self-regulate or exert effortful control. Thus, the attentional abilities we measure probably rests on a strong gene $\times$ environment interaction.

The DRD4 gene, related to the dopamine system, is an illustrative example of how genes can influence attention, especially the executive network (Posner et al., 2013; Rothbart and Posner, 2015). A specific part of the DRD4 gene (the 7-repeat allele) has been linked to risk taking behavior and also to ADHD. This DRD4 7-repeat allele also interacts with environmental factors. In a study on parental training trying to decrease children's externalizing behavior, a positive effect was noted only for children carrying the 7-repeat allele.

Aspects of attention

Novelty attracts attention

Novel objects and novel locations affect attention from birth although the parallel process of familiarity also exerts a strong influence on attention during the first months of life. Behaviorally, novelty preference can be reliably observed from approximately 4–6 months of age. Identification of new information leads to faster and more reliable orienting, activates the alerting system, recruits available relevant brain resources (working memory and sustained attention), and prepares the system to encode new information that, in a second step, might be transferred to long-term memory.

The identification of a new object is governed by two processes. The first process to emerge is the ability to identify a new location. This ability is related to the control of eye movements and is, in some form, present at birth. It is observable through inhibition of return (IOR), which means that the visual system resists going back to a previous location; new locations are more attractive. The second process, the identification of a new object, is a slower-developing visual skill. It is usually established by 4–6 months and is related to the development of object recognition. This ability is observable through visual recognition memory.

Attention to faces and novel objects co-acts when, for instance, an adult demonstrates a new action with an object. In an eye-tracking study, Koch et al. (2018) found that 12- and 16-month-old infants shifted their attention from the presenter's face to the object as soon as the action was demonstrated for the first time. However, after repeated demonstrations, the infant's attention reverted to the presenter's face which suggest a dynamic relationship over time between attention to the action and the face. This reorientation to the face might "be driven by social interest and attempts to understand the presenter's intentions" (Koch et al., 2018, p 197).

Memory and attention

From 3 to 4 months and onward, the infant's ability to process new information has proved to be robust. This can be shown in paired-comparison experiments or tests when the child's preferential looking pattern is observed. Typically, a child prefers new information (a novel stimulus) in comparison with familiar information, which makes it possible for the researcher to calculate a novelty preference score. This score provides an index of the child's visual recognition memory, since the child must be able to compare the new information with the remembered familiar target in order to show a preference for the novel one (Morgan and Hayne, 2011). Measures of novelty preference (and therefore visual recognition memory) in early infancy have been found to be a significant predictor of intelligence, nonverbal communication, and language (e.g., Rose et al., 2012). As an example, it has been reported that visual recognition memory measured in infancy predicts receptive language at 3 years even when controlling for general IQ. These results suggest that attentional and memory capacities tapped by visual recognition memory as measured by novelty preference are important for later developing communication skills.

Visual recognition memory seems to tap into the very basic functions of our nervous system but exactly how these early attentional and memory processes affect later cognitive processes is still unexplained. One clue to an explanation has been proposed by Colombo and collaborators (2001) who found that, at 4 months, attention termination explained more of the observed variance in a novelty recognition task than sustained attention. The research group interpreted their findings as supporting the "hypothesis that individual differences in the disengagement underlie the relation between look duration and cognitive performance in early to mid-infancy" (Colombo et al., 2001, p 1605).

Pupil dilation and attention

Infants visual processing time is related to how well they learn and remember. This means that longer looking times should be related to increased memory for the information the infant is attending to, which is also supported by empirical research. However,

apart from time, infants' quality of attention is also related to learning, which can be assessed through pupil dilation. The human pupil dilates in response to changes in luminance, but an increase in pupil size is also evident when people experience internal arousal, conduct mentally challenging tasks, and when processing a stimulus that is novel and motivating. This makes pupillometry an appealing complementary measure in infancy research on visual processing. Looking time and pupil dilation were compared in an imitation study with infants (Sonne et al., 2016). The infants saw a three-step action on a screen and were tested on delayed recall two weeks later. Only pupil dilation showed a correlation with memory performance, suggesting that the quality of attention might be a better measure compared to looking time, if we want to understand the relation between attention and learning.

Attention and learning

The directed-attention model

The memory span for objects is around one item at 6 months and two to three items at 1 year. This means that infant learning and infants' complex social responses are carried out with a memory and attention system that is very limited compared to older children and adults. A model for how this can be achieved has been proposed by Reid and Striano (2007, see also Michel et al., 2015) who outline a five-stage directed-attention model of infant social cognition. The model describes five perceptual stages that infants typically will master within the first year of life. The model provides an attempt to integrate known perceptual and cognitive abilities and skills with the amazing social competence seen in the human infant. In brief, the proposed stages or phases are:

- 1 *Detection of socially relevant organisms.* Infants are born with a nervous system that directs them toward the social world. They are sensitive to distinctions between animate and inanimate objects, they prefer moving stimuli to static, biological motion to nonbiological motion, they are sensitive to the human voice, to rhythm, and they imitate (mimic) facial gestures.
- 2 *Identification of socially relevant organism.* The process to differentiate individual persons starts immediately at birth. The newborn infant rapidly learns to identify the mother's voice, smell, and face. More complex responses, such as imitation, are also used early on (from 6 weeks) to identify persons.
- 3 *Assessment of the locus of attention.* Once the socially relevant organism has been detected, infants start to "attend toward characteristic that index the locus of attention of the observed organism" (Reid and Striano, 2007, p 105). Eye and head movements provide important information to the infant in early social interactions. The infant's predisposition to enter into the social interactions with the caregiver is probably driven by intrinsic and biologically based motives to communicate with other humans.
- 4 *Detection of object-oriented attention.* Already at 4 months infants can use an adult's gaze to learn about objects and, by 8–9 months, objects become parts of highly motivating joint-attention encounters. Objects or an aspect of the environment that has been highlighted through joint attention with an adult will become more salient to the infant who will direct more of his or her attention to those objects/areas. The first sign of an emerging declarative memory is observed at 6 months through the child's ability to act on a memorized representation after a delay (deferred imitation).
- 5 *Inference of goals and/or prepare response.* Toward the end of the first year, infants begin to respond differently to accidental and intentional action. The child now starts to understand that people have goals that motivate their actions. The capacity of working memory increases, which makes it possible for the child to hold more than one piece of information online simultaneously.

Dyadic attention

The interaction between a parent and an infant is characterized by rhythm, intimacy, and emotional exchange, the so-called proto-conversations. This interaction is encouraged by the parent through smiles and increased gaze in such a way that the interaction is prolonged and infants are active partners in this interaction, creating turn-taking sequences. Trevarthen (2011) suggests that infants from an early age have the capacity to engage in communicative acts and to respond to the communication of others. In these early interactions, the infant and the parent are attuned to the subjective state of the other. Thus, the infant is aware of the parent's attention and is also responding to this attention. Trevarthen describes this awareness as primary intersubjectivity, which is supported by the parent by responding to the social initiatives from the infant. Both parent and infant are sensitive to the contingency and quality of this interaction and will soon develop expectancies of specific patterns of communication from each other. This is evidenced by using still-face conditions where the parent is either not responding to the infant's communication or by using a double-video-technique showing a pre-recorded interaction creating unsynchronized turn-taking from both partners. Furthermore, infants very early learn to anticipate, not only contingent communicative patterns, but also contingent behavior from their parents. When an infant's distress is accompanied by a parent's soothing, the association between arousal, the parent's response, and subsequent relief is easily learned – soothing is anticipated by the infant already at 4 months of age.

This intrinsic communication with human beings could not be enhanced without the infant exploring the physical environment. With an increasing ability of motor control, the child will experiment with its own actions on objects such as mobiles and thereby develop an early understanding of agency according to physical cause and effect. With the growth of contingent perception, the infant is able to accompany this physical agency into detection of cause and effect/reciprocity with partners into further developed nonverbal turn-taking sequences – both vocal and with objects (like pushing a ball back and forth). This means that infants are able to coordinate their attention with another person and understand the framework in which communication takes place between two persons.

Joint attention

Nine-month-old infants begin to understand that actors are pursuing goals and they combine the awareness of outside objects, events, and persons in order to share and coordinate their attention or perception of goal activities, the so-called joint attention. By performing joint activities such as building a tower of bricks or rolling a ball back and forth, infants start to understand the concept of sharing goals. This is accompanied by attention skills such as following the other persons' eye-gaze or pointing in order to direct others attention to objects in the surrounding environment or trying to modify a persons' behavior with gestures.

The earliest sign of triadic attention is seen when infants start to follow others' gaze toward external objects or events. Through gaze-following the infant can identify what other people are attending to and can begin to compare their own visual information with other person's attention. Gaze-following in early infancy has been suggested to lay the foundation for both referential communication and social cognitive development ([Brooks and Meltzoff, 2015](#)).

Attention skills that are initiated by the child (e.g., pointing) develop slightly later than behaviors that are responses to others (e.g., gaze-following). The capacity to direct another persons' gaze to objects by the infant's own interest develops between 9 and 12 months and infants can use the pointing gesture for different purposes, for both sharing attention and requesting. There is an interactive relationship between infant behavior and caregiver response in the development of pointing. Research shows that an infant's understanding of another's pointing gesture predicts their own production of pointing, suggesting that pointing is learned through observing and imitating the gesture in others. However, when infants begin to use pointing, their parents increase their own use of pointing, suggesting that the infant's ability to direct others' attention also influences their social and communicative environment ([Ger et al., 2018](#)).

It has been argued that declarative pointing, in contrast to imperative pointing, relies on the understanding of others as mental agents and is driven by a motivation to share attention and interest with other persons; it has therefore been suggested to be especially difficult. In typically developing infants, the motivation to share attention and interest is probably strong and declarative gestures are common, in contrast to children with social impairments like autism. An experiment with 12-month-olds has revealed that the social context is crucial for the number of pointings the infant makes ([Liszkowski et al., 2004](#)). Only when the adult was active in sharing the infant's attention to the event the infant pointed at, did the infants' pointing increase. The interpretation of this result was that the infant did not only want to direct the adult's attention, but also wanted to share this attention.

It has been shown in several studies that the capacity for joint attention is an important precursor to later-developing language and cognitive skills. Together with early memory measures (e.g., visual recognition memory and deferred imitation) joint attention probably lays the ground for later-emerging social cognition including intentional understanding. A study by [Brandone et al. \(2020\)](#) investigated this relationship longitudinally. They showed that the tendency to engage in joint attention episodes around 6 months of age predicted the infants' understanding of intentional actions three months later.

Intention requires attention

Humans are special in their capacity to understand others' intentions. It can be argued that infants, by the time they begin to follow and direct others' attention, have acquired some understanding of others as intentional agents and that other people act on the basis of their own view of the world. From 6 months of age, infants follow another person's gaze to objects in the surrounding environment, but they have been shown to pay more attention to where the head is turning, whereas older infants pay more attention to the eyes indicating understanding of the adult's intentions. When adults turn to an object with their eyes open or closed it was observed that infants by the age of 12 months looked at the target if the adult turned to it with open eyes but did not do so if the person turned to it with eyes closed ([Meltzoff and Brooks, 2007](#)).

Furthermore, studies have revealed that infants during their second year start to understand the intention behind an action and not only the action they actually have seen; when 18-month-old infants were observing an action that the adult failed to perform they did not imitate the failure, instead they performed the complete action ([Meltzoff, 1995](#)). Using anticipatory looking, studies have revealed that infants as young as 10 months differentiate between failed and successful actions ([Brandone et al., 2014](#)). The infants saw an actor repeatedly reach for a ball and either retrieved it or not. Ten-month-olds (but not 8-month-olds) looked at the goal of the action (the ball) both when the actor successfully reached it or when the actor failed, indicating that they interpreted the actor's intention and not the outcome.

Decades of research show that children are around 4 years of age when they understand that others' mental states can differ from their own and that another person's behavior is based on their beliefs, even if the child knows they are incorrect. More recent studies have suggested that some understanding of this "false belief" might be present already in infancy. These studies all use nonverbal methods, such as violation-of-expectation. According to the violation-of-expectation paradigm, infants pay more attention to situations that are surprising to them or contradict their expectations of how other people will act. Although numerous studies have found similar results using different nonverbal methods, the specific findings have also been difficult to replicate and, to date, there is still debate about the scope and limitations of the social cognitive understanding in early infancy (see [Poulin-Dubois et al., 2018](#)).

Digital media and attention

The fact that attention depends on different systems that develop over time raises obvious questions about how the new digital world influences children over the course of development ([Courage, 2017](#)). The newborn capacity for attention is limited and is to a large extent in the hands of the parents. However, some capacity to orient and attend do exist early which will help the infant in his/her socio-cognitive development. An important aspect is that the executive attention network develops relatively slow. That is,

the abilities important for controlling one's own attention, to switch attention between events, and to stop attending (attention termination) are difficult tasks for the very young child.

Even if digital media is attractive there is no scientific support for the idea that children below the age of three learn better or faster via digital media (see [Barr and Linebarger, 2017](#)). In fact, research has shown that children below that age actually need more exposure to take in new information compared with a real 3D-world situation when an adult can scaffold attention by creating an interaction that supports joint attention.

Another aspect of the new digital world relevant to attention processes are the popular action video games that often require fast switching between tasks, keeping strategies in mind, and online planning. These are tasks that, besides involving many important brain areas, to a large extent rely on the attention networks described in this chapter. Some studies have found that the type of multi-tasking required by action video games have positive effects on some vision skills (e.g., tracking peripheral objects) as well as on reaction times ([Rothbart and Posner, 2015](#)). However, the findings are not clear cut. It seems as if the positive findings are more related to the ability to orient whereas training effects of the executive network are less certain.

Compensatory systems

Questions have been raised as to whether the sensory system can compensate for a deficit in one area, since it is striking how blind people can use auditory and tactile cues for orienting themselves and getting information. In one study ([Forster et al., 2007](#)), it was shown that spatial tuning of tactile attention is more accurate in early blind individuals compared to sighted individuals when areas for Braille reading are stimulated, suggesting a compensatory scaffolding for individuals who have experienced visual deprivation from birth or early infancy. The plasticity of the brain, which makes it possible to overcome deficits, is underlined by the fact that the sensory systems work together, especially, according to the dimensions of space, time, and intensity. This so-called redundant, amodal information is seen as a cornerstone of perceptual development. For example, when an adult takes a child's hands and uses them for clapping, auditory, visual, and tactile systems are involved, discerning both rhythm and rate to the child.

Final remarks

With increasing age, looking and attention come more and more under voluntary control. The child becomes more able to decide what to focus on; he or she will, by 4–5 years of age, be able to choose to attend to information even if it is boring. However, attention never becomes completely voluntary. Processes like novelty preference and habituation influence attention throughout life.

An increasingly important area for future research is to create a better understanding of how digital media influence children's development from infancy to adolescence, to adulthood. To what degree is media helpful and to what degree might it create or hinder a child's attention abilities? This requires deeper understanding, not only of brain development, but also of psychological, sociological, and societal facts that all might influence the use or abuse of digital media.

In the future, we will hopefully also develop more specific knowledge about specific genes and their impact on attention and on gene $\times$ environment processes (see [Posner et al., 2014](#)). This might help us gain a better understanding of how attention develops, how individual differences in attention capacities evolve, how experience and biology co-act to create alertness and sustained attention, or the ability to initiate attention in another person – knowledge that will also be highly relevant for both our understanding of typical development as well as for children with various disabilities such as ADHD or autism.

Acknowledgment

The authors wish to acknowledge the late professor Tomas Tjus who co-authored a previous version of this paper (published in *IEE* third Ed). Although the text is thoroughly updated it still owes much in scope and rigor to his detailed and insightful work. The work of M.H. was supported by grants from the Marcus and Amalia Wallenberg Foundation, Sweden (MAW 2018.0084) and the Swedish Research Council (Grant no.: 2016-01033).

Introduction

Cognitive load theory can be subdivided two complementary aspects: A cognitive architecture based on (a) our knowledge of human cognition and evolutionary psychology and (b) a series of cognitive load effects based on instructional hypotheses generated by the cognitive architecture and tested using randomized, controlled experiments. The ultimate aim of both the cognitive architecture and the data is to provide prescriptive, instructional procedures. The cognitive architecture is discussed first.

Human cognitive architecture

While human cognitive architecture is immensely complex, only parts of our cognitive system are directly relevant to instructional issues and so it is those parts with which we are primarily concerned. Evolutionary psychology can be used to provide one of the dividing lines between categories of information.

Evolutionary educational psychology

Evolutionary educational psychology can be used to divide knowledge into biologically primary knowledge, which is a category that is less relevant to instructional issues, and biologically secondary knowledge, which is a category that is the subject of most instruction (Geary, 2008, 2012; Geary and Berch, 2016).

We have evolved to acquire biologically primary information. It is acquired effortlessly and unconsciously. Examples are learning to listen to and speak a native language, acquire general problem-solving and thinking skills, store knowledge for future use, and use that knowledge to plan future events. Because primary knowledge and skills are acquired unconsciously, they do not need to be taught and indeed, for that reason they cannot be taught because they will already have been acquired when needed. Primary knowledge and skills are modular with no relations between many of them. For example, our ability to generalize a skill from one set of conditions to another may be unrelated to our skill in planning future events. Different primary skills with distinct, unrelated functions are likely to have evolved during different evolutionary epochs.

Secondary knowledge is acquired for cultural reasons and differs from society to society. Unlike primary knowledge, it is not acquired automatically without conscious effort on the part of the learner. It also is unlikely to be acquired without deliberate instruction. Examples of biologically secondary information can be found in virtually all curricula of all educational institutions. Schools, as well as all other educational institutions, were developed precisely to teach biologically secondary information. Without such institutions, only tiny proportions of any general population will acquire the knowledge imparted by educational institutions. For example, reading and writing were invented several thousand years ago but only became common in some populations at the beginning of the last century with the advent of mass education. Without mass education, the majority of any general population would remain illiterate. The contrast with listening and speaking could not be more stark. Every developmentally regular child will learn the immensely complex tasks of listening and speaking their native language automatically, without formal instruction, because humans have evolved to do so since the advent of the human species. Indeed, most of us would have no idea how to teach children how to organize their tongues, lips, breath and voice in order to speak. We do not need to teach this skill because it is biologically primary and so acquired automatically. We do need to teach children how to write along with all of the other skills taught in education and training institutions because such skills are biologically secondary, considered important for our societies, and otherwise would not be acquired.

Generic-cognitive knowledge and domain-specific knowledge

There is another dividing line providing categories of information. That categorization scheme overlaps heavily with biologically primary and secondary information. Generic-cognitive knowledge leads to very general skills such as general problem-solving skills, thinking skills, or self-regulatory skills. They can be contrasted with domain-specific skills that apply to a very limited set of circumstances. For example, using means-ends analysis to solve a wide variety of diverse problems (Newell and Simon, 1972) provides an example of a generic-cognitive skill that can be contrasted with learning how to solve a limited range of algebra problems by multiplying out a denominator. (A means-ends problem-solving strategy involves considering a current problem state, comparing it with a problem goal or a sub-goal state, extracting differences between the two states, and lastly, attempting to find problem-solving operators that reduce differences between the two states.)

Because of their scope, generic-cognitive skills are much more important than domain-specific skills. Everyone needs to know how to solve problems using means-ends analysis in order to survive but can, of course, survive without knowing how to multiply out a denominator in order to solve a problem. Arguably, the importance of generic-cognitive skills is such that we have evolved to acquire them automatically and unconsciously—they are biologically primary. In contrast, we have not specifically evolved to acquire domain-specific skills such as multiplying out a denominator in an algebraic equation. Domain-specific skills must be explicitly taught and consciously learned as biologically secondary skills (Tricot and Sweller, 2014).

Instructional implications of the distinction between biologically primary, generic-cognitive skills and biologically secondary, domain-specific skills

As indicated above, biologically primary, generic-cognitive skills are central to human functioning. It is essential for us to be able to regulate our mental processes or solve novel problems that we encounter. In contrast, we can survive if we have not acquired biologically secondary, domain-specific information such as how to manipulate algebraic equations, or if we do not know the causes of World War 1. Because of this differential level of importance, there sometimes is a tendency to place a greater emphasis on the acquisition of generic-cognitive, primary skills than domain-specific, secondary skills (Tricot and Sweller, 2014). That emphasis can be seen in the labeling of generic-cognitive skills as “21st Century skills” with the implication that, for example, explicitly teaching students thinking skills should be part of modern curricula.

Nevertheless, despite the critical importance of generic-cognitive skills, if they are acquired automatically and unconsciously, then attempts to teach them are unnecessary and will inevitably fail in the sense that people taught such skills will show no greater ability to use them on novel, transfer tasks than people not provided instruction. (A novel transfer task is one that is completely different from the task used to teach the generic-cognitive skill. It needs to be different to provide evidence that any improvement really is due to the acquisition of the generic-cognitive skill and not due to the acquisition of domain-specific information.) The failure late last century and early this century of attempts to teach generic problem-solving skills is one of a long list of such failures. For example, the ground-breaking work of Newell and Simon (1972) used sophisticated computational models to establish means-ends analysis as a critical problem-solving strategy. Since that time, as far as I am aware, there has not been a single study demonstrating enhanced problem-solving skill following tuition in the use of the strategy. We all need to use the strategy in order to survive and so tuition in the use of the strategy is pointless. We have all evolved to acquire this complex, sophisticated, generic-cognitive

strategy without instruction. Of course, if a body of evidence indicating successful instruction of generic-cognitive skills becomes available, theory will need to follow the data.

Processing biologically secondary information

The biologically primary and secondary systems are closely connected with little or no secondary knowledge acquired without simultaneous use of the primary system. There is a specific cognitive architecture consisting of several biologically primary cognitive processes and structures associated with acquiring biologically secondary, domain-specific information. That architecture is closely analogous to the architecture that governs the processes of evolutionary biology. Both evolutionary biology and the structures and functions associated with the acquisition of biologically secondary information constitute examples of natural information processing systems (Sweller and Sweller, 2006). When applied to human cognition, that information processing system has instructional implications that are central to cognitive load theory (Sweller et al., 2011, 2019). The cognitive architecture required to process biologically secondary information can be described by five basic principles associated with (a) the acquisition of novel information represented by the borrowing and reorganizing principle and the randomness as genesis principle, (b) the organizing and storing of that information for later use represented by the narrow limits of change principle and the information store principle, and (c) the retrieval of that information when required, represented by the environmental organizing and linking principle.

The borrowing and reorganizing principle

In order to adequately function in most societies, humans need to obtain vast amounts of biologically secondary information. The vast bulk of that information is obtained from other people by listening to what they say or reading what they write. That information can be reorganized to accord with currently held information and stored for later use. Education and training systems were invented to facilitate this process. We have evolved to obtain information from others so while the information obtained can be biologically secondary, the principle itself is primary. We are one of the few species that naturally obtains information from other members of the species. Like all evolved skills, we vary in our ability to obtain information from other people.

The randomness as genesis principle

Information from others is not always available. When unavailable from others, information can be generated during problem solving using a random generate and test procedure. We do not need to teach people how to randomly generate moves, test them for effectiveness, and retain effective moves while rejecting ineffective ones. This general problem-solving ability is again, a biologically primary, generic-cognitive skill that does not need to be taught because it is acquired automatically. It is an essential process in the initial generation of knowledge. Without it, there would be no knowledge to acquire using the borrowing and reorganizing principle discussed above.

The narrow limits of change principle

All novel information initially must be processed by a limited capacity, limited duration working memory before it can be stored in long-term memory. We cannot hold more than about 7 items in working memory at a time (Miller, 1956), process more than about 3 or 4 items at a time (Cowan, 2001) where processing involves organizing, comparing or working on items, and cannot hold items in working memory for more than about 20 s without rehearsal (Peterson and Peterson, 1959).

The information store principle

To be subsequently useful, information acquired by the borrowing and reorganizing principle and the randomness as genesis principle must be stored. Very large amounts of information acquired by one of these two principles can be permanently stored in long-term memory during learning. There are no known limits to the amount of information that can be stored in long-term memory. The importance of this principle to activities such as problem solving became apparent following the work of De Groot (De Groot, 1965; De Groot and Gobet, 1996) who found that acquired problem-solving skill in chess came from the storage in long-term memory of many thousands of chess-board piece configurations taken from real games. Subsequent work demonstrated that the same storage of domain-specific information underlaid skill in a variety of academic areas (Chiesi et al., 1979; Egan and Schwartz, 1979; Jeffries et al., 1981; Sweller and Cooper, 1985).

The environmental organizing and linking principle

Once novel information has been processed by working memory and stored in long-term memory, it can be transferred back into working memory. Environmental signals inform us which organized information stored in long-term memory is required at any particular time. That information, transferred from long-term to working memory, can be used to govern actions appropriate to the environment that triggered the transfer. Unlike when dealing with novel information, working memory has neither capacity nor temporal restrictions when dealing with organized information transferred from long-term memory (Ericsson and Kintsch, 1995). In this way, learning transforms us. We can carry out actions that in the absence of the information stored in long-term memory would be impossible.

Instructional consequences of human cognitive architecture

Based on the above cognitive architecture, the purpose of instruction is to assist learners to transfer domain-specific, biologically secondary information from working to long-term memory. Once stored in long-term memory, the information can be transferred back to working memory to generate and govern appropriate action.

Some information naturally consists of numerous elements that need to be processed simultaneously because they interact. For such information, element interactivity is high resulting in a high intrinsic cognitive load. For example, most geometry materials consist of high element interactivity information. To understand a geometry theorem such as “the external angles of a triangle equal the addition of the opposite internal angles” and to use that theorem to solve problems, learners need to understand all of the elements that constitute a particular diagram and to simultaneously process the elements of any statements associated with the diagram and combine the elements of the diagram with the elements of the statements. The working memory load can be overwhelming due to a high intrinsic cognitive load. In contrast, learning the names of theorems and constructs also can be difficult because there are many to learn such as the “external angles of a triangle theorem” but the difficulty is not due to a heavy working memory load because the various names do not interact. The name of each theorem can be learned independently of the name of the other theorems. When learning the names of theorems, element interactivity is low resulting in a low intrinsic cognitive load (Chen et al., 2015, 2016a,b; Sweller, 2010).

Intrinsic cognitive load only can be changed by changing the nature of the information or changing the expertise of learners. Expertise is increased by altering the contents of long-term memory. The information store and the environmental organizing and linking principle alter what constitutes an element. With increasing expertise, information that previously consisted of multiple elements can be transformed into a single element that incorporates the element interactivity of sub-elements, thus reducing intrinsic working memory load.

One aim of instructional design is to optimize intrinsic cognitive load. If intrinsic cognitive load is too low, learners will not learn as much as they could while if it is too high, working memory may be overwhelmed resulting in a reduction of learning.

Extraneous cognitive load also can be changed by changing element interactivity (Sweller, 2010). Unlike intrinsic cognitive load that only can be changed by altering what is taught or by increasing expertise, extraneous cognitive load is imposed by instructional design procedures such as the way information is presented or the activities required of students and can be changed by altering those procedures. The aim is always to reduce element interactivity associated with extraneous cognitive load.

Some cognitive load effects

All of the empirical work associated with cognitive load theory concerns cognitive load theory effects that are demonstrated by using the theory to generate a new instructional design that either optimizes element interactivity associated with intrinsic cognitive load or reduces element interactivity associated with extraneous cognitive load. The effectiveness of a new design is tested against a more traditional procedure. Randomized, controlled experiments are used exclusively to demonstrate cognitive load theory effects. Several of the more important effects are discussed next.

The worked example effect

Learning can be facilitated more if learners study worked out problem solutions than if they attempt to solve the same problems themselves. The worked example effect is demonstrated when novice learners who are presented high element interactivity problems to solve obtain lower scores on a subsequent problem-solving test than learners presented the same problems as worked examples that they are asked to study (Cooper and Sweller, 1987). Conventional problem solving using a means-ends strategy (Newell and Simon, 1972) imposes a heavy, extraneous cognitive load that interferes with learning. Studying worked examples reduces that cognitive load.

The problem completion effect

The problem completion effect (van Merriënboer and Krammer, 1987) has a similar rationale to the worked example effect except that rather than presenting learners with a full worked example, they are presented with a partially completed worked example that they are asked to complete. Compared to full problems, learning is facilitated (van Merriënboer and Krammer, 1987).

The goal-free effect

Since conventional problem solving imposes a heavy extraneous cognitive load, alternative problem-solving strategies that reduce the cognitive load should be effective. Goal-free problems are structured so that rather than having a conventional goal such as, *What is the velocity of the object?* in a kinematics problem, the goal is changed to, *Calculate the value of as many variables as you can.* When a problem is worded in this way, it is impossible to use a means-ends strategy to reduce the difference between a current problem state and the goal state because the goal state is not specified, which reduces cognitive load. Goal-free problems facilitate learning (Sweller et al., 1983).

The redundancy effect

When worked examples or any other form of instruction includes essential information along with unnecessary information, learning is inhibited compared to the presentation of the essential information alone. A comparison of the same information

with and without redundancy yields the redundancy effect if less information improves test scores (Chandler and Sweller, 1991). There are different forms of redundancy. Some examples are presenting the same information in different modalities such as identical written and spoken text during PowerPoint presentations (Kalyuga et al., 2004), adding text to a self-explanatory diagram that does not require text to be fully understood (Chandler and Sweller, 1991), or adding cartoons to text. All have the same effect of depressing learning by having learners process additional, unnecessary information in limited working memory.

The element interactivity effect

All cognitive load effects rely on element interactivity being high. If element interactivity is low, an effect may disappear or even reverse. For example, the worked example effect only occurs when students are attempting to learn to solve difficult (high element interactivity) problems. The issues associated with element interactivity can be seen when the worked example effect appears to contradict another effect, the generation or testing effect. This effect occurs when learners presented a task such as learning a new vocabulary, learn more if they are asked to generate answers to questions on information with which they have some familiarity, rather than re-study the information. Chen et al. (2015, 2016a,b) obtained a conventional worked example effect with geometry learners studying worked examples performing at superior levels to learners solving the equivalent problems. In contrast, they obtained a reverse worked example effect (a generation effect) when tested on their knowledge of the names of the theorems and of the geometric shapes that they had to learn in order to solve the problems. Knowledge was increased more if they had to generate the names of the geometry theorems and shapes rather than re-studying those names. As indicated above, learning to solve a problem is high in element interactivity because each move is related to all of the other moves and so imposes a high working memory load. Each name of a geometry theorem or shape on the other hand, can be learned independently of all the other names.

The expertize reversal effect

This effect is a particular example of the element interactivity effect (Chen et al., 2017). As indicated previously, element interactivity can be altered by altering the information that is being processed in different tasks (Chen et al., 2015, 2016a,b). Element interactivity also can be altered by altering the levels of expertize of learners. The same information processed by someone with a higher level of expertize will have a lower level of element interactivity due to the environmental organizing and linking principle. According to that principle, large amounts of information that incorporate interacting elements can be transferred as a single element from long-term to working memory. As a consequence of these changing levels of element interactivity associated with expertize, effects such as the worked example effect can disappear or reverse with increasing expertize. With higher levels of expertize, solving problems may result in more learning than studying worked examples—a reverse worked example effect (Kalyuga et al., 2001).

This reversal associated with increased expertize can occur with all cognitive load effects. It is due to the redundancy effect. For a novice, studying a worked example is an important way of acquiring knowledge to be stored in long-term memory. For a more expert learner in a particular domain, studying a worked example is a redundant activity. More expert learners already know how to solve the problem. They only need to practice solving it so that they can do so automatically (Schneider and Shiffrin, 1977; Shiffrin and Schneider, 1977) without imposing an unnecessary load on working memory.

The guidance fading effect

Based on the expertize reversal effect, it follows that an effective instructional sequence should begin with full worked examples followed by guidance fading using completion problems and ending with full problems. There is considerable evidence for the effectiveness of this sequence (Renkl and Atkinson, 2003).

The split-attention effect

This effect (Tarmizi and Sweller, 1988) occurs when learners must split their attention between multiple sources of information in order to understand it. If for example, information includes a diagram and associated text that are unintelligible in isolation and so must be mentally integrated to be understood, learning will be facilitated by physically integrating them. Note that the relations between the two sources of information are critical to the split-attention effect. If, for example, the diagram is fully intelligible in isolation without the associated text, then the text is redundant and should be eliminated in line with the redundancy effect, rather than being integrated in line with the split-attention effect.

The self-management effect

While the split-attention effect indicates that physically integrating information facilitates learning, students will frequently come across information that is presented in split-attention format. Roodenrys et al. (2012) hypothesized and demonstrated that teaching learners to physically integrate split-attention information would be beneficial.

The modality effect

Under split-attention conditions where two sources of information such as a diagram and text are unintelligible until they have been mentally or physically integrated, rather than physically integrating them, to reduce cognitive load, the text can be presented in spoken rather than written form. The presentation of both auditory and visual information increases available working memory resources by using both auditory and visual processors. The use of dual modalities in this fashion increases learning compared to the use of the visual modality alone (Mousavi et al., 1995).

The transient information effect

Spoken information is transient. What we hear now continually disappears to be replaced, most commonly, by new information. Writing was invented to convert transient, spoken information into permanent information. The modality effect assumes that spoken information will be short and easily processed in working memory, thus transferring some of the load from the visual to the auditory processor. If the textual material is long and complex rather than being short and simple, it will impose less of a cognitive load when presented in permanent, written rather than transient, spoken form. This result was demonstrated by [Leahy and Sweller \(2011\)](#). The modality effect was obtained with short, simple textual material but a reverse effect with superior visual only information was obtained with long, complex material that was difficult to process in transient, spoken form. Similar differences were obtained using animated information which is similarly transient in nature by [Wong et al. \(2012\)](#).

The variability effect

The same information can be presented under a higher rather than lower variety of conditions. With higher variability, students might learn that a problem such as, $a/b = c$, solve for a , is identical to, $x/y = z$, solve for x , and to, $c = a/b$, solve for a . The greater the range of such problems that learners are exposed to, the greater the variability and the cognitive load imposed. The increase in cognitive load is intrinsic because learners must not only learn the mechanics of solving this category of problems, but also must learn to distinguish which problems belong to the category and which do not. [Paas and van Merriënboer \(1994\)](#) found that this increase in intrinsic cognitive load facilitated learning. Intrinsic cognitive load needs to be optimized, unlike extraneous cognitive load that requires reduction.

The isolated elements effect

Similar to the variability effect, this effect is due to optimizing intrinsic cognitive load except that the effect relies on a reduction rather than an increase in intrinsic cognitive load. Some highly complex information cannot be appropriately processed in working memory due to high levels of element interactivity. If a task includes a large number of interacting elements, learning may be enhanced by ensuring that the constituent elements first are entrenched in working memory by presenting them to students in isolation before they are presented in full, interacting form ([Pollock et al., 2002](#)). Presenting interacting elements in isolated form initially reduces intrinsic cognitive load to a level that allows processing.

The imagination effect

If learners are asked to imagine a procedure rather than merely study it, they may learn more. This effect is particularly prone to expertize reversal. To obtain any advantage from imagining a procedure, learners must be sufficiently expert to be able to imagine the procedure. If they cannot imagine the procedure, studying is superior to imagining ([Cooper et al., 2001](#)).

The collective working memory effect

Collaborative learning can be effective because it allows differential knowledge between learners to be combined, using in effect, a single, collective working memory consisting of the limited working memory of all collaborators ([Kirschner et al., 2011, 2018](#)). The effect is not obtained in the absence of differential knowledge between participants. Collaboration tends to be ineffective if students have similar knowledge in long-term memory ([Retnowati et al., 2017, 2018](#)).

The human movement effect

Due to the transient information effect, animations can frequently increase cognitive load and decrease learning. One exception seems to occur when the animation depicts human movement ([Van Gog et al., 2009](#)). We seem to have evolved to readily assimilate depictions of human movement without an excessive working memory load.

The spacing effect

Recently, cognitive load theory has been used to explain the spacing effect that occurs when learning that is spaced with gaps between events enhances learning compared with the same events being massed without gaps ([Chen et al., 2018](#)). It was suggested that when working memory is overloaded, its resources are depleted resulting in less learning, with recovery after rest. Spaced learning allows that rest and recovery while massed learning does not, providing an explanation of the spacing effect.

Conclusion

The cognitive architecture used as a base for cognitive load theory has generated a range of novel instructional procedures. The assumptions that instructional design should be primarily concerned with domain-specific, biologically secondary information and that when dealing with such information, the information processing procedures follow those used by evolutionary biology, has resulted in instructional procedures that differ from many alternative treatments. The effectiveness of those instructional procedures has been supported by multiple, randomized, controlled studies. Through cognitive load theory, the known characteristics of human cognitive architecture can be used to generate novel instructional designs.

While cognitive load theory has generated many cognitive load effects, the manner in which it has done so should be noted. All cognitive load theory effects have limits imposed by the cognitive architecture that gave rise to them. No cognitive load effect should

be used without considering that architecture. Many new cognitive load effects were discovered as a consequence of the limits of older effects with cognitive architecture used to determine the nature of those limits. For example, the worked example effect was first demonstrated using algebra problems such as $(a + b)/c = d$, solve for a . A natural assumption was that the effect should be obtained using other problems such as geometry, in which a diagram is characteristically provided followed by separate statements concerning that diagram, or kinematics problems in which a statement is provided followed by algebraic procedures related to the statement. It took several years of replication failures to realize that the conventional manner in which worked examples in these areas were presented did not reduce extraneous cognitive load. The conventional way of demonstrating algebra worked examples did not incorporate split-attention. The conventional way of demonstrating geometry or kinematics problems did incorporate split-attention. If a worked example incorporated split-attention, it would not reduce working memory load compared to solving a problem. Once split-attention was eliminated from worked examples, the worked example effect could be readily demonstrated in new areas (Tarmizi and Sweller, 1988; Ward and Sweller, 1990).

This pattern of replication failure followed by the discovery of a new effect based on our knowledge of human cognition has been repeated on numerous occasions. Arguably, cognitive load theory has been developed more by replication failures than by any other factor.

Introduction

The benefits of creativity are numerous and varied. They include adaptability, flexibility, mindfulness, problem solving, health, and even quality of life (Runco, 2022). Creativity also contributes in several ways to learning and is an important topic for education. The relationship with learning is particularly important because it suggests that there are ways to fulfill creative potentials. The causal relationship between learning and creativity is reciprocal. Not only does learning sometimes support creativity, but creativity can also ensure that learning is meaningful.

This chapter explores the connections between creativity and learning. It begins with an overview of creativity research. It then reviews the learning theories that have been applied to the topic of creativity, and reviews the theoretical basis explaining how the creative process ensures that learning is authentic and meaningful. A particular focus is the 4P framework for studying creativity (i.e., creative person, creative product, creative process, and creative press or place). This chapter also reviews the operant view of creativity wherein insight may be the result of the spontaneous integration of previously learned responses. It explains how the intrinsic motivation so often involved in the creative process may be explained by reinforcement histories. It then goes into detail about how understanding experience depends on the creative process and how individuals create meaning as they interact with the world. Various implications for education are noted.

Overview of creativity research

Research on creativity has grown in a dramatic way in the last few decades. It has become an interdisciplinary field. There are neuroscientific, genetic, economic, developmental, clinical, historical, cognitive, educational, and cross-cultural studies of creativity (Runco, 2022). Perhaps the best way to examine the various perspectives on creativity involves the 4P framework for studying creativity, originally proposed by Rhodes (1961) but updated several times. Rhodes identified the four key strands of creativity research: investigations of the creative *person*, the creative *product*, the creative *process*, and the creative *press* (which is now usually described as the creative *place*). He used the term *press* because, at the point in time when he proposed the framework, it was common to describe situational pressures on human behavior in that manner. Importantly, some of these press factors have a universal impact, while others known as “beta press influences,” have only idiosyncratic impact, depending on how an individual interprets them. This is a very important point because interpretation is involved in the process whereby creativity is related to learning. This is examined in more detail below.

Studies of the creative person usually focuses on personality traits. There are several specific traits which seem to make up the core characteristics of creativity. These include openness, autonomy, flexibility, and intrinsic motivation. Personality tests are often used in this kind of research. The limitation of the personality approach is that traits are now viewed as interacting with situational factors, and thus not explanatory in and of themselves. Personality might provide creative potential but does not guarantee actual creative performance. This may explain why some students have several of the core characteristics but are not in fact manifestly creative. The concept of creative potential is also examined further below.

Studies of the creative product often focus on outcomes, and may therefore quantify paintings, musical scores, novels published, citations given to an individual scientist, or some other outcome of an individual's work. The focus is on the tangible, or at least objective, outcome. This approach has the advantage of being objective because products can be counted, and this provides objective data. The disadvantage is that products do not offer any information about the process that led to the product. Thus there is objectivity, but not much information provided about the mechanism or what students actually do when they are creative. In addition, product studies have a kind of sampling bias because they usually focus on mature individuals. The products studied tend to be socially recognized, including those outcomes listed above (citations, novels, etc.) and require time, expertise, and maturity to bring them to fruition. Children's products are occasionally studied (Rosenblatt and Winner, 1988; Runco, 1989) but they cannot be evaluated with the same professional standards as those from adults.

Studies of the creative process examine stages of the creative work. They may use something like Wallas' (1926) famous four-stage theory. It described how creative work starts with some sort of preparation (which may include problem discovery or problem identification), then moves to incubation, the result being an illumination (or a-ha!), which requires some sort of verification. Many contemporary views of the creative process use or extend Wallas' stage theory (see Runco, 1994). Theories of innovation, for example, often refer to the same four stages, but then they add a fifth stage, namely *implementation* (see Amabile, 2020 for recent discussion of this stage model).

There is also the divergent thinking approach to creativity, which is essentially a process theory as it describes how individual's thinking progresses and how people may associate one idea to the next. The process is called divergent because it moves in different directions. This may be contrasted with convergent thinking, where an individual takes several pieces of information and the thinking converges on a correct or conventional response or answer. Divergent thinking goes in different directions, some of which may be original. Divergent thinking is aligned with creativity because it is easier to find original ideas when the process is divergent rather than convergent.

Studies of the creative place examine conditions which may either support or inhibit creativity. Creativity is often inhibited, for example, when there are evaluations, so an individual is unable to follow his or her intrinsic interests, or when there are expectations of conventional behavior. Conventional behavior is by definition normative and thus nearly the opposite of the originality that is required for creativity. There are conditions that support creative behavior, including those which allow autonomy and independent thinking. There are a number of measures for assessing particular situations (e.g., the work setting or the classroom) to determine if creativity is supported or inhibited (Amabile, 1990; Rickards and Jones, 1991; Runco et al., 2016).

Runco (2007) reorganized the "4P" framework. This was done, in part, to acknowledge the idea presented above that some influences on creativity merely provide the potential for creativity but do not guarantee actual creative performance. Indeed, the main idea in this modified framework is that there is a distinction between potential and actual performance. Those two things are used as the most general categories of a hierarchy, with personality, press, and process all subsumed under *creative potential*, and products, along with "persuasion" (Simonton's (1988) idea that creative people and products change the way that others think) and creative achievement under the *creative performance* category. The significance of the hierarchical framework, which implies 6Ps instead of 4Ps, is in its suggesting that creative potential might be supported such that it eventually leads to actual creative performance. This is one way to think about education—as a method for fulfilling creative potentials so students will eventually actually earn socially recognized creative achievements. Creative behaviors that are beneficial but personal rather than socially recognized are also important.

Before turning to the relationship between creativity and learning, two other points about creativity research must be made. First, originality, mentioned several times above, is a prerequisite for creativity. It is necessary but not sufficient. There is more to creativity than originality. The "standard definition" of creativity requires originality (or novelty) and effectiveness (or utility or fit) (Runco and Jaeger, 2012). Without effectiveness of some sort, original things might be useless or just crazy. Simonton (2012) suggested that there should be a third requirement for creativity, namely surprise (as in non-obvious), and Kharkhurin (2014) pointed to aesthetic value and authenticity. The latter makes sense because many Eastern cultures actually value authenticity more than originality (e.g., Tan, 2016) and authenticity is a part of the self-actualization that Rogers (1959) and Maslow (1968) found to characterize highly creative individuals. "Value" has also been nominated as a requirement of creativity, but that suggestion has been met with criticisms of subjectivity (Harrington, 2018; Weisberg, 2018).

The second important point is that, when there is a need for precision, it is best to avoid the noun *creativity*. This is because the noun is used in so many ways, and not all of the meanings are interchangeable, as is obvious from the various perspectives captured by the 4P and hierarchical frameworks. What is said about the creative product may not apply well to the creative process, just to name one example. Note that this example suggests a useful alternative to using the noun: the adjective *creative*, as in creative process, creative achievement, creative activity, creative thinking, and so on. Using the adjective *creative* requires more precision and avoids confusion.

The relationship between creativity and learning

Theories of creativity have clear implications for learning, which of course is an important part of education. As a matter of fact, a case can be made that authentic learning depends on a creative process. This view is explained below and put into the context of the operant theory of learning. There are other theories of learning, but some only explain reflexive and involuntary behaviors, which means that they do not relate to creative behavior, while there are a number of connections between operant theory and the creative process.

Operant theory and creativity

At first blush, it may seem that traditional learning theories do not say much about creativity. This is because some of them (e.g., classical conditioning) only describe changes in reflexes, and those which focus on voluntary actions only describe changes in overt behavior. Skinner's (1974) theory of learning has sometimes been called *Behaviorism*, so named because its emphasis on maximal objectivity meant studying only behavior that was overt and observable, and therefore amenable to objective assessment. Many people prefer the label "operant theory" to Behaviorism. An operant is a voluntary behavior that is emitted in order to obtain

a reinforcer or to avoid a punisher. Whichever label is used, operant theory is distinct from other kinds of learning theories, most notably the Pavlovian school, also known as Classical conditioning, and Social Learning Theory.

Even with the emphasis on overt, maximally objective behavior, operant research has contributed to our understanding of the creative process. Some of this research uses Skinner's idea that behavior is displayed because of reinforcement history, not because there are immediate contingencies involved. Skinner thought that reinforcement histories can explain things like the creative efforts of the so-called *starving artist*. That refers to a stereotype of a creative individual who is starving in the sense that he or she is doing original things that are not being rewarded. Without rewards, in the form of money or similar support, the individual has little and is starving. Why would an artist invest in work that is not being supported? A personality psychologist may say that the artist is following intrinsic rather than extrinsic rewards. The operant view is that it is not intrinsic motivation but is instead a history of reinforcement that continues to support the artistic efforts or other expressions of originality (Runco, 2019). In this light a child might have been heavily rewarded for being original and continues to act in an original fashion, or even choose a line of work that allows originality, because of that history. This makes the most sense if, as a child, the individual received intermittent reinforcement, for that leads to behavior that is resistant to extinction.

This is an intriguing explanation for certain original behaviors, but a question arises because empirical research has demonstrated that extrinsic rewards tend to undermine creative work (Amabile, 1990; Eisenberger and Shannock, 2003). In fact, extrinsic rewards may eliminate the intrinsic motivation for creativity efforts. If individuals are intrinsically motivated, but then receive extrinsic rewards for that behavior, they may forget that they were initially intrinsically motivated (Hemmessey and Zbikowski, 1993). This is known as *overjustification*.

The operant idea of reinforcement history explaining the original behavior of starving artists is theoretical, but there is also empirical work using operant techniques to control thinking that is relevant to many creative achievements, namely *insight*. Insight is not the same thing as creativity, but many breakthroughs seem to have been the result of insight (Gruber, 1988). Insights involve a sudden breakthrough and a dramatic shift in one's thinking. Insights are sometimes called "a ha!" moments and are synonymous with the illumination stage mentioned earlier. One explanation for them is that there are changes in the individual's cognitive structures. Operant investigations have examined insight because it is operational and observable. In one example, Epstein (1990) started with a methodology that had been used in famous research conducted in the 1940s by Wolfgang Kohler. Kohler worked with an ape named Sultan. This research had a large impact at the time because it demonstrated that Sultan could be insightful. That was significant because, up to that point, scientists believed that apes were only capable of trial and error and were not capable of insight. Kohler disproved this with his demonstration that the ape Sultan was capable of insight and did not rely on trial-and-error thinking. Kohler demonstrated insight in a series of observational studies. In one, a banana was placed outside of Sultan's cage, beyond his reach. Sultan had various things in the cage with him, including a stick. The stick was not the only thing in the cage, but Sultan did not experiment with all available objects, which a theory of trial and error would predict. Instead, he stood at the bars of the cage, observed the banana, which he very much wanted, and looked back and forth from the banana to the stick. Without trial and error, Sultan eventually walked over to the stick, took it back to where he was standing at the bars, and used the stick to extend his reach and pull the banana toward him. He solved the problem in an insightful way and was rewarded with a banana.

In another experiment, a banana was hung from the ceiling of Sultan's cage, again out of reach. This time the cage contained various crates and boxes. Sultan did not use trial and error and experiment with all possible objects but instead looked at the boxes, then looked at the banana, looked back at the boxes, and so on. He eventually picked up one box moved it underneath the banana, went to another box and stacked it on top of the first box, climbed on top of both boxes, and was able to reach the banana.

Epstein (1990) conducted similar work with pigeons. This work is remarkable because it is one thing to accept that apes have thinking skills that are similar to that of humans, but pigeons? From the operant perspective what is remarkable is that the insightful thinking could be manipulated by controlling environmental conditions, including reinforcers. Epstein started by making a small banana out of pigeon chow. This banana was hung from ceiling of a cage. A pigeon was conditioned such that they learned that the banana shaped object was actually pigeon chow. Their wings were clipped, in a humane fashion, so they could not fly when they were placed in a cage with the "banana" hanging from the ceiling. Before they were placed in the cage they were also conditioned to push small boxes around, and, in separate experimental conditions, trained to stack the boxes. Importantly, the conditioning of these behaviors—pecking a banana shaped object, pushing boxes, and stacking boxes—was such that there was only one target behavior at a time. The learned behaviors were, then, discrete and independent. Yet when the pigeons were placed in the cage with the hanging banana, they seemed to do what Sultan had done. They looked at the banana, looked at the boxes, back and forth, and fairly quickly pushed the boxes, stacked them, hopped up, and pecked the banana. No trial and error. This led Epstein to conclude that seemingly insightful behaviors can in fact be explained in terms of reinforcement histories and that insightful solutions might reflect the "spontaneous integration of previously learned responses." According to Epstein, there was no reason to attribute any great intellectual ability to the pigeons. Instead it is reasonable to explain their behavior, which was very similar to Sultan's, as a result of their learning. Note that what was learned was insight, not creativity per se.

Piaget's constructionist theory and creativity

Like all work with subhuman species, the operant work just reviewed may not generalize to humans. Jean Piaget's work (1976), in contrast, involved children. Piaget's view of development is constructionistic. Useful learning, for Piaget, requires that the individual construct knowledge for him- or herself. This construction may be viewed as a creative process. New knowledge may be created as the individual interacts with the environment. The title of Piaget's (1976) monograph, *To Understand is to Invent*, captures this nicely.

Piaget (1976) argued that education is often superficial. In particular, he criticized learning that depends on memorized information. Useful learning, in contrast, involves the construction of knowledge. Piaget's ideas about learning and what he called adaptation were extensive, in part because he developed them over several decades. There are misunderstandings about his theory, and some of these reflect the fact that what he wrote early on was not identical to what he wrote later, after he had more data and his theory evolved. It is also important to note that his data were not from controlled research. He relied on a method called *empathic inference*. This involved carefully observing children under certain conditions and inferring what they must have been experiencing cognitively and how that led to the actions observed.

After observing quite a few children Piaget inferred that children develop through stages. The first is sensorimotor, the next is preoperational, followed by the concrete operational stage, and finally, formal operations. Sensorimotor thought is all about the body and movement. It may not even seem like thought, and it certainly is not like the thinking of older individuals, but the children are processing information and very early on form cognitive structures (schema, schemes, or schemata) which represent what they understand about their bodies. The preoperational stage occurs when a child develops the capacity to use symbols. This allows them to think using language, but also to think using various other symbol systems. Concrete operational thinking allows the child to understand classifications and to conserve quantities, while formal operations allows the individual to think in a way that is not unlike formal logic. The formal operational individual may also think deductively and about hypothetical things. Most important for the present purposes is that individuals develop structures—they structure their thinking—as they grow older. According to Piaget, the kind of structures and cognitive operations they can use are constrained by biological age, as well as experiences. This is of course where learning comes in, and where the connection of learning with creativity is apparent. Simply put, new structures are created. In other words, the individual uses a creative process to construct new structures, and those structures are indicative of learning.

Piaget had his own view of how individuals benefit from experience and preferred the label “adaptation.” A close examination of adaptation provides further detail about what is involved in creative thinking. The first important point, implied above, is that adaptation is very different from memorization. Adaptation leads to new structures, new meaning, and new understandings of the world. The second of those things, understanding, is special because it points to the reason why humans do in fact expend effort to adapt. Why do we allocate time and energy? So we can make sense of our experiences. This begins with the assimilation of information, and then an accommodation of that information. The first of these, assimilation, requires that an individual have new experiences, new in the sense that they are not understood. This does create a problem because how can the individual think about something that he or she does not understand? The answer is that the new information is altered, and some of it may be ignored. The individual alters information such that it can be brought into his or her cognitive system. Once it is in the system, it can be processed and the existing structures can accommodate to that new information. New structures may be formed or existing structures can be modified to differentiate so the new information is understood. The construction of new understandings is a creative process.

Importantly, individuals invest resources into adaptation because they are intrinsically motivated to do so. Piaget did not use the phrase “intrinsic motivation,” but he did propose that students did not need to be motivated to learn. They are genetically predisposed to maintain an understanding of their experiences, and this leads them to adapt to new experiences. No one likes to be in a situation that they cannot understand. For this reason everyone is motivated to develop and maintain an understanding of experience. That motivation is not a result of extrinsic factors such as bonuses, grades, salaries, points, or rewards of any sort. This is important and has obvious implications for education. As Piaget put it, the difficulty with education is to find things that challenge individual students. If they are challenged, and the challenge is slightly above their current level of functioning, they will invest the resources in order to adapt and create new understandings. Since those are new, they are original, and if they do in fact make sense, they are effective. Thus, they satisfy the standard definition of creativity, with its two requirements.

Elkind (1981) extended the Piagetian view of education and pointed to communication as the key educational issue. He described how children are in stages that are different from the educator (e.g., a concrete operational student with a formal operational teacher) and thus the student's thinking is a very different from that of the teachers. The students are “cognitive aliens.” This often makes it very difficult for the teacher to understand the student, which in turn means that communication is difficult. Runco and Beghetto (2018) examined similar issues but suggested that the creative process could be used by teachers to better communicate and understand. Their theory distinguished between *primary creativity*, defined as that which results from a student's constructing new knowledge via an original and effective interpretation of experience, and *secondary creativity*, which is the teacher's creative interpretation of the student's ideas.

Interestingly, teachers' thinking may differ from that of students but also from that of parents. Teachers' thinking (or “implicit theories”) of children's creativity have been systematically examined, with the results indicating that teachers give the most weight to creativity as expressed in social actions (e.g., creative behavior which is unusual and expressed by very few students). Parents, in contrast, tend to be more concerned about the cognitive bases of creativity (e.g., problem solving). These differences are important because it can be quite beneficial when teachers and parents are coordinated in their efforts to support children's development. Additionally, generalization is most likely when the efforts of teachers match the efforts of parents, so what is learned in school is also supported when students are at home.

Teachers generally value creativity and believe that it should be supported in the classroom, but at the same time, they very often do not realize that creativity depends on autonomy, divergent thinking, and intrinsic motivation (Westby and Dawson, 1995). This can make it very difficult for teachers to encourage creativity. It is understandable in that autonomy and these other qualities can be difficult to appreciate when teachers are working with groups of students. Each of these things would be much easier if the teacher could work with one child at a time. In a group, it is much easier for all students to follow a set curriculum and work at the same pace.

Discussion

This chapter has touched on many of the important concepts used in research on creativity. It covered the 4P framework and its extension into a hierarchy, summarized the standard definition of creativity and possible extensions of it, and used findings concerning intrinsic motivation, insight, and problem discovery as part of the review of possible relationships between learning and creativity.

Implications for education are various. The 4P and 6P theories suggest that classroom settings should allow for autonomy and avoid unnecessary evaluation. They also suggest that openness, autonomy, and flexibility are especially important characteristics, and as such should be supported, and that divergent thinking and insightful thinking are both related to the capacity for creative problem solving. The “press” research on creativity suggests that there are individual differences among students which mean that not all students will react the same way to classroom conditions. Interactions between a student’s personality and particular conditions should be expected. The ideas about intrinsic motivation, from both Amabile and Piaget, suggest that educators should find ways to allow students to follow their interests, when possible, and that intrinsic motivation is more likely to lead to creative thinking, compared with grades and other extrinsic rewards.

There are several ways of looking at the relationship between creativity and learning. There is learning, as in operant conditioning involving reinforcers and punishers, but there is also adaptation in the Piagetian sense. The latter is especially important because it explains how new understandings are actively constructed by individuals. The construction of meaning is a creative process. New understandings and meaning are created. These may eventually lead to creative products and socially recognized creativity, but the new understandings are of course important in and of themselves. They allow us to cope with challenges and deal with everyday experience. Creativity is often a personal thing. Social recognition is sometimes important, but not always.

One thing that should be clarified is that adaptation is not always creative. The two processes are not synonymous. Adaptation implies a reaction by the individual, and creativity is sometimes proactive rather than reactive. Also, recall here that the creative process often depends on problem discovery. This would occur in a proactive matter, before a problem has been identified. In addition, on a general level, adaptation could lead a student to conform rather than to originality. This kind of adaptation is behavioral and thus unlike the cognitive process Piaget (1976) described, the idea being that if an adaptive student finds him- or herself in a situation where there is pressure to conform, the adaptive response may be to go with the crowd. It is possible certainly that the individual has the ego strength to resist pressures to conform and does not conform, even if adaptable. It would probably be useful for the teacher to display creativity him- or herself and thus provide a model of creativity. Other descriptions of how adaptability may be related to creativity have been provided by Cohen (1989) and Russ (1998).

Teachers can themselves model creative behavior. This will convey the idea that creativity is a valuable thing, and students are likely to internalize those values. The modeling might demonstrate how to use various tactics that facilitate original thinking. Runco (2017) reviewed a number of such tactics. These included changing one’s perspective when faced with a problem, collecting more information, putting the issue or problem aside (to allow incubation), questioning assumptions, and changing the problem such that it more easily allows original options. It might be argued that, while tactics are helpful, they are not as important as the other direction of effect mentioned herein, whereby creativity leads to meaningful learning. This is why the idea of creating personal understanding and Piaget’s (1976) “to understand is to invent” was discussed in detail. This process of finding meaning and creative new understandings can help many times each day and can support the most important parts of life, including the recognition of one’s own meaning in life. Such meaning in life is one of the more important things that education may support. It can support it by encouraging creative thinking which in turn allows students to create meaning. This is just one of the numerous and varied personal and social benefits to the creative capacity. Much can and should be done to support the creativity of students.

Recent research and its discussion confirm that although curiosity and interest have similar characteristics, they are distinct constructs, and may involve different types of engagement (e.g., [Hidi and Renninger, 2019, 2020](#); [Murayama et al., 2019](#); [Shin and Kim, 2019](#); see also discussions in [Peterson and Hidi, 2019](#)). Nonetheless, the specific educational implications of these findings for practice have received relatively little attention. Given that basic research does not always map directly to practice, in this chapter we address what is understood about such applications. We also consider what still needs further study. We begin by defining and describing the characteristics of both curiosity and interest, and by highlighting the similarities and differences between them. To illustrate and consider these constructs, we draw on case materials. Following this, we discuss the educational implications of each, as well as the needed next steps in their research.

Definitions, characteristics, and case examples

Curiosity and interest describe psychological states, and share characteristics such as being universally motivating and not requiring extrinsic rewards. They are each experienced as energizing, and as directing information search—an activity that is rewarding because of its association with the reward circuitry in the brain (e.g., [Gottlieb et al., 2013](#)). However, curiosity and interest represent different types of information search. Information search related to curiosity is associated with a desire to resolve uncertainty, or to close a knowledge gap (e.g., [Berlyne, 1960](#); [Grossnickle, 2016](#); [Jirout et al., 2018](#); [Loewenstein, 1994](#); [van Schijndel et al., 2018](#)), whereas information search linked to interest is general and ongoing ([Ainley and Hidi, 2014](#); [Renninger and Hidi, 2019, 2020](#)). We note that curiosity, or openness, is also studied in personality theory as a trait of individuals ([Digman, 1990](#)); however, we do not address the study of curiosity as a trait in this chapter. Interest can be initiated by the triggering of situational or momentary interest that may continue to develop into a relatively stable individual interest, or by an aspect of the experience of engaging with an already existing interest ([Hidi and Renninger, 2006](#); see [Renninger and Hidi, 2016, 2022](#), for an update and overview). Thus, in addition to describing a psychological state during engagement, interest also refers to individuals' motivation to reengage with the content of interest over time.

Triggers commonly associated with curiosity have been uncertainty, novelty, surprise, or complexity; they characteristically create an information gap (e.g., [Berlyne, 1960](#); [Jirout et al., 2018](#); [Liquin and Lombrozo, 2020](#); [Smock and Holt, 1962](#)). In surveys, indicators of curiosity have also included confusion, and/or frustration as associated with the tension introduced by the knowledge gap before it is resolved (e.g., [Lamnina and Chase, 2019](#); [Litman and Jimerson, 2004](#)). Once the knowledge gap is resolved, the experience of curiosity becomes associated with positive affect (e.g., [Manz and Suárez, 2018](#); [Tang et al., 2020](#)).

Although surprise and complexity may also be triggers for interest, there are many other triggers, such as hands-on activity, group work, technology, self-related information processing, etc. ([Hidi and Renninger, 2019](#); [Renninger and Hidi, 2021](#); see [Renninger et al., 2019](#) for a detailed discussion of triggers in a classroom). Indicators of interest that together have been used to assess the development of interest in surveys, observational protocols, interviews, etc., include the frequency and depth of individuals' engagement with particular content, as well as whether their engagement is voluntary and independent when opportunity allows ([Renninger and Hidi, 2016](#); [Renninger and Wozniak, 1985](#)). It should be noted that this approach differs from assessment of interest based only on affect (e.g., How much do you like doing math?, [Eccles et al., 1993](#), p. 834).

As indicated in [Table 1](#), curiosity and interest differ not only with respect to their affective valence, but also in their duration, goals, and required level of knowledge (see extended discussions in [Grossnickle, 2016](#); [Hidi and Renninger, 2020](#); [Shin and](#)

Table 1 Characteristics of curiosity and interest.

	<i>Curiosity</i>	<i>Interest</i>
Most common triggers	Few: Uncertainty, novelty, surprise, and complexity	Many: Surprise, complexity, hands-on activity, group work, technology, self-related interventions such as personalization, utility-value, etc.
Duration	Short-lived	On-going
Goals	Information search to close a knowledge gap	General information search
Knowledge	Moderate level	All levels
Affect	Discomfort and tension prior to resolution of knowledge gap, followed by positive affect	Primarily positive

Kim, 2019). In the following, case materials from second grade students are provided in order to allow more nuanced consideration of the characteristics of curiosity and interest development, and their implications for practice.

Curiosity

Keisha's curiosity was piqued during a science lesson on simple machines, and later resolved. She rotated through different stations set up throughout the classroom that included opportunities to work with inclined planes, pulleys, and levers. At the pulley station, she stopped and was confused about why a bucket of water was hard to lift on its own, but felt easier to lift when attached to the pulley. Keisha wrote down her question on her worksheet as she had been told to, but must have been thinking about it even while she was supposed to be exploring inclined planes, as she was not really attentive to them.

During the whole class discussion, Keisha asked, "Why does the bucket feel lighter using the pulley?" Her teacher explained that pulleys redirect force and showed an instructional video on how pulleys work. This response resolved the question because she was given the information that she needed. She asked no further questions about pulleys, and did not pursue additional information or opportunities to work with pulleys after that class ended.

The trigger for Keisha's curiosity about pulleys was uncertainty (e.g., Engel, 2011; Jirout et al., 2018). However, for Keisha to seriously engage with the information and the video that her teacher provided, it appears that she may have needed more knowledge than she had (Grossnickle, 2016). Guidance in her work with the hands-on activities would have been very helpful to her (Furtak et al., 2012). If someone had picked up on and responded to her uncertainty about working with the bucket of water, Keisha might have continued to seek out information about pulleys, possibly triggering subsequently her interest development in pulleys or mechanics. In order to trigger her interest, her teacher might have offered information that it could feel easier to pull down on an object than to lift the same object up, and then could have invited her to try using some different objects on the pulley (see discussion in Luce and Hsi, 2014). In subsequent classwork, the teacher also could have included activities that would provide Keisha (and the other students) with additional opportunities to work with pulleys. For example, the teacher might have engaged all of the students in follow-on activities such as figuring out whether including many or fewer wheels changed how easy it was to lift an object, or assigning reading related to mechanics. Importantly, the teacher could make this kind of an addition to the curriculum, and may well trigger and sustain Keisha's interest in the pulleys.

Triggered situational interest that is sustained

On her walk to school one morning, Rosa saw a river otter. She was brimming with questions about the mammal she saw when she got to school. She asked her teacher what the animal was, and why it was on land. She said she thought that it could swim, and that it was really cute and playful. She wanted to know where it lived, and what it might eat. Her teacher was friendly and told Rosa that the animal she saw was likely to be a river otter.

She explained that there are a lot of otters out there, and asked Rosa to hang up her coat and take her seat. Rosa did as she was told, and joined her friends at their table. She began talking with them about the picture books they were looking at. It appeared that even though her interest in the river otter had been triggered, it would not be sustained, and that this was a missed opportunity to support her to develop her interest.

However, a few weeks later, when her teacher told the class that they would be working on the River Project, Rosa seemed to have returned to thinking about the otter. The teacher explained that each student would be researching a different mammal that lives along the river. The design of the project included each student reading several books on the mammal they had chosen, taking notes on its appearance, size, habitat, adaptations, as well as its prey and predators. The project would culminate with a written report and a presentation during an all-school assembly. Almost immediately, Rosa excitedly announced that she would be studying the river otter.

The River Project research provided an opportunity for Rosa to engage in information search that enabled her to answer her earlier questions, tackle those that were listed by her teacher, and to generate some additional questions to address on her own as well. Her project and presentation far exceeded the stated expectations for the project.

Rosa's interest in the river otter appears to have been triggered when she noticed that it was on the riverbank and was not in the water. It may have helped to trigger her interest that she thought the otter was cute and playful. She did not know what the mammal was. At first, it looked like her interest had only been triggered, and that she would not return to related information search. However, the River Project research provided an opportunity for her to re-engage in trying to learn about the otter.

Even though she did not know much at all about river otters, Rosa had enough information to ask questions and to begin work on the animal research project independently; there is no minimal amount of knowledge that is required for sustaining and developing interest once it is triggered (Grossnickle, 2016). It is likely that for her the most meaningful new information about the river otter would include answers to the questions that she had asked her teacher. Her questions addressed information that she wanted to understand and, as such, were self-related (Hidi et al., 2017, 2019; Renninger and Hidi, 2021). In answering those questions, as well as those that were assigned, Rosa had a base of knowledge from which to generate and pursue answers to additional questions for her report. The quality of the report signaled that her developing interest benefitted her learning, as well as her performance (e.g., Jansen et al., 2016).

Sustained and developing individual interest

Dom has been working on a collaborative writing project with his best buddy, and seemed to be willing to talk about writing with anyone who will listen. Early in the school year, he and his buddy had written a fictional story about a group of friends who went trick-or-treating at a haunted house. After working on "their book," Dom eagerly shared it with the rest of the class. He (and his buddy) reveled in the positive feedback that they received and the interest of their peers. Dom has continued to write more stories with his buddy. He has also begun writing stories on his own. Recently, he has been asking others to read them and to give him feedback, so that he can make them "even better."

There appear to be multiple triggers for Dom's interest in writing. (We note that even though triggers are typically studied individually in the laboratory, outside of the laboratory, multiple triggers for interest co-occur and provide support for sustaining triggered interest; Renninger et al., 2019; see discussion in Renninger and Su, 2012). One trigger appears to have been the opportunity to work together with his best buddy on a story (Bergin, 2016; Renninger and Hidi, 2016). Working together may also have been a chance for them to remember and describe their own experiences trick-or-treating and visiting a haunted house, as self-related information is also a trigger for interest (Renninger and Hidi, 2021). The positive feedback and interest from their peers that followed served as additional triggers for interest, and likely contributed to Dom's own sustained, and then developing interest in writing (Hidi et al., 2002; Hidi et al., in press). In working collaboratively, they were able to pick up on and stretch each other's ideas (Webb and Palincsar, 1996), which likely contributed to their developing knowledge about the process of writing. Moreover, as they were drawing on information that they already knew, no additional information was required (Hidi and Anderson, 1992; Grossnickle, 2016).

In summary, as Dom's and Rosa's cases both illustrate, when interest is triggered and sustained, learners readily begin to generate their own curiosity questions—questions that are novel to them (although they may not be novel to others) (Renninger, 2000). These questions may be verbalized or may just inform successive instances of their information search. Importantly, the individuals do not need support to ask and pursue answers to their questions, nor do they need a certain level of knowledge to continue meaningful and deepening interaction with the content. By contrast, once curiosity is resolved, as in Keisha's case, it is not likely to result in further engagement, as the information gap has been closed. If, however, the questions informing the triggering of curiosity were to provide a basis for continuing re-engagement, this subsequently could lead to the triggering of a situational interest, and in turn, ongoing information search and the development of interest (Hidi and Renninger, 2019; Luce and Hsi, 2014). In such situations, curiosity could be considered a type of trigger for interest.

Educational implications

Luce and Hsi (2014) suggested the potential of using students' spontaneously generated questions as guides for educators wishing to support the development of interest, as these provide information about the specific connections that learners are making to content. During discussions with sixth graders about their photojournalism essays, the researchers tracked the youths' curiosity expressions about causal mechanisms, teleological explanations, and inconsistencies in observations. They noted that the youths readily generated spontaneous curiosity expressions, and furthermore that the youths' curiosity expressions ranged in type and were idiosyncratic. Although they called these questions curiosity expressions, we suggest that their data provide yet another illustration of how individuals' information search informs the course of interest development (see related discussions in Alexander et al., 2019; Azevedo, 2013; Hecht et al., 2021). We also draw attention to the self-related nature of spontaneous expressions or questions of this sort, noting that because they are the individuals' "own" questions, and are based on the individuals' own information search, they are likely to be triggers for interest and ongoing learning (e.g., Harackiewicz et al., 2008; Bernacki and Walkington, 2018; see discussion in Renninger and Hidi, 2021). The self-related quality of interested engagement is critical to individuals voluntarily continuing to re-engage with content. Such reengagements provide opportunities for exploration, practice, and developing conceptual understanding.

Curiosity development

As depicted in [Table 2](#), the focus of curiosity research that has addressed educational practices drawing attention to uncertainty have ranged from more to less direct instruction in support of asking questions. Some have specifically prescribed curiosity-promoting instruction in schools, such as modeling comfort with uncertainty and question generation (see [Grossnickle, 2016](#); [Jirout et al., 2018](#); [Loewenstein, 1994](#)), whereas others have investigated the design of successive engagements with complexity (e.g., [Engel, 2011](#); [Manz and Suárez, 2018](#); [van Schijndel et al., 2018](#); [Wu et al., 2018](#)).

Studies of curiosity have generally suggested that promoting curiosity in the classroom requires optimal levels of uncertainty, which can be achieved by helping students to prefer and tolerate greater levels of uncertainty, even if negative feelings are triggered (e.g., [Engel, 2011](#); [Jirout, 2020](#); [Jirout et al., 2018](#)). Supporting curiosity development by teaching students to question has been shown to positively influence levels of curiosity and engagement in school (e.g., [Wu et al., 2018](#)), and also to have some limitations. [Van Schijndel et al. \(2018\)](#), for example, showed that although curious children learned more, they did not have a higher quality of exploration than those with less curiosity. In other words, the children closed their knowledge gaps and learned, but their search for information was not qualitatively better than that of those who had less curiosity.

[Clark et al. \(2019a,b\)](#) used [Rothstein and Santana's \(2011\)](#) Question Formulation Technique (QFT), a question-brainstorming intervention, in two studies designed to promote curiosity. The QFT includes six components: (1) question focus (the teacher or student introduces a prompt that is not a question), (2) question production (students generate as many questions as they can), (3) categorization (marking questions as either closed or open-ended and changing one into another as needed, discussing the advantages and disadvantages of each type), (4) question selection (students choose their top priority questions), (5) next steps (students plan how they want to use their questions to inform their learning), and (6) reflection (students reflect on their learning from the QFT). In the first study, [Clark et al. \(2019a\)](#) reported that teaching the adolescents they studied to ask questions positively influenced their curiosity. However, in a follow-up study, they further explained that the procedure of teaching question-asking had a negative impact on students' cognitive engagement and self-efficacy ([Clark et al., 2019b](#)).

Together with elementary science teachers, [Manz and Suárez \(2018\)](#) developed a method to support learners to ask their own self-related questions and, on the basis of these, to re-engage uncertainty, and search for additional information. The researchers described three strategies for supporting the second-grade students with whom they were working to develop what they termed "scientific uncertainty." These were: first, introduce a complex phenomenon; second, follow this with phases of experimentation with that phenomenon, and finally, leverage the variability that emerges in students' ideas. To this end, following the students' experimentation with the phenomenon, teachers then encouraged the students to reflect on what they had learned by asking them to say what they might change in their experiments the next time. The students were supported to formulate additional research questions and to choose what they wanted to study. This meant that they re-engaged the uncertainty that characterizes the scientific process and deepened their knowledge. Keisha, in the case described earlier, may have needed this type of support in order to continue work with the bucket and the pulley. We suggest that Manz and Suárez' strategies for promoting scientific uncertainty could be understood as supports for triggering and developing interest. Thus, when uncertainty is resolved, given that there is encouragement to sustain engagement, situational interest development can be triggered ([Renninger and Hidi, 2016](#)).

Interest development

Interest develops in relation to individuals' ongoing search for information that is not focused only on closing an information gap. As depicted in [Table 3](#), studies of interest development and classroom practice have generally focused on providing support for learners to engage in meaning-making about the content of their potential interest. Support to develop an interest may be facilitated

Table 2 Examples of studies suggesting educational approaches for promoting curiosity.

Approach	Context	Measures	Findings
Create optimal levels of uncertainty, teach tolerance for uncertainty (Jirout and Klahr, 2012 ; see also Jirout et al., 2018)	Laboratory	Task performance	A medium level of uncertainty leads to exploration.
Incorporate successive engagement in science instructional activities (Manz and Suárez, 2018)	Classroom	Teacher report	Successive engagement contributes to uncertainty and positive student experience.
Guide curiosity (Engel, 2011)	Laboratory	Task performance	Modeling curiosity promotes exploration.
Provide opportunities to invent in the curriculum (Lamnina and Chase, 2019 ; see also Glogger-Frey et al., 2015)	Classroom	Experiment, questionnaire, task performance	Engaging in invention leads to greater curiosity and transfer of learning.
Teach questioning (Clark et al., 2019a,b)	Classroom	QFT intervention, questionnaire, teacher fidelity check	Teaching questioning may positively influence curiosity, but also may negatively affect self-regulation and cognitive engagement.

Table 3 Examples of studies suggesting educational approaches for promoting interest.

<i>Approach</i>	<i>Context</i>	<i>Measures</i>	<i>Findings</i>
Include social support, autonomy, and choice (Nolen, 2007)	Classroom	Longitudinal, mixed methods	Higher levels of interest in writing.
Include text attributes, insert elaboration after main points (Hidi and Baird, 1986)	Classroom	Expository text	Increases interest, increases recall, less forgetting
Provide hands-on activity, computers, puzzles etc. (Swarat et al., 2012; see also Mitchell, 1993)	Classroom	Questionnaires, interviews	Triggers interest.
Incorporate multiple approaches to working with content (Xu et al., 2012)	Classroom	Interviews, observations	Provides new exposure, encourages independence, and promotes interest.
Encourage self-related reflection (Renninger et al., 2014; see also Chin and Chia, 2006)	Out-of-school workshop	Task-based interviews, observations, classroom artifacts	Increases in learning and interest.
Personalize context (Bernacki and Walkington, 2018)	Classroom	Math units, surveys, and tests	Triggers situational interest and increases performance.
Enable participation with others in inquiry-based, project-based or problem posing collaborations and inventions (Dohn, 2013)	Field trip	Observations, interviews	Triggers interest and positive affect
Include new information and meaningful context (Crouch et al., 2018; see also Hoffmann, 2002)	Classroom	Surveys, course performance, interviews	Increases in performance and in interest; differences based on more or less initial interest in physics.
Promote utility-value (Hecht et al., 2021)	Classroom	Utility-value intervention, questionnaires	Increases task interest and performance, specifically for students with less confidence.

or designed by other people and/or the nature of the tasks and activities the learners engage (e.g., Mitchell, 1993; Swarat et al., 2012). Learners also may be supported to self-generate connections to the content (e.g., Hecht et al., 2021).

Learning environments that promote interest development enable individuals to work with the content in multiple ways. For example, by providing tasks such as projects that allow different and repeated opportunities for working with content, as well as various formats for working with and thinking through content such as demonstrations, text, or group projects; see developed descriptions in Nolen, 2007; Pressick-Kilborn, 2015; Xu et al., 2012. They usually include richly textured tasks such as projects or activities, and social support from peers and/or educators. As Xu et al. (2012) showed, the benefit of these types of task is that they lead learners to continue to re-engage, and are beneficial for learners with varying levels of readiness.

Nolen (2007) described two 3-year longitudinal studies conducted in multi-age classrooms and the development of their interest in reading and writing. She demonstrated how situational factors were more likely to trigger and then sustain student interest when the classroom instruction took the form of a literate community—a context in which the community provides the basis for shared learning activity, rather than more traditional teacher-directed practices which highlighted the importance of learning reading and writing. The study of the literate community clearly demonstrated that supporting interest in that type of setting led students to develop their interest. It indicated that children whose interest in reading was initially triggered by social factors, such as peer excitement around popular book series, was then shown to be sustained through discussions and opportunities to share. As the students read more books that were similar to those they thought of as “favorites,” they began to develop a stable interest. Moreover, certain conditions, such as autonomy support and positive experiences with content, facilitated students’ situational interest to develop. Projects that involved choice were supportive of the students’ taking initiative; these were supportive of developing interest (Hidi and Renninger, 2006). It also appeared that time to work on collaborative projects led the youth to describe writing as a fun activity, similarly to the case of Dom and his buddy described above.

On the strength of her data, Nolen (2007) argued that environmental support for student interest is critical, especially in writing as writing is a challenging and effortful task. Nolen’s data also suggested that students are able to generate questions independently. This is especially the case when they are working with tasks that are complex or challenging enough to enable them to continue to stretch their understanding of the content of their interest (Renninger, 2010). In addition, Nolen’s data highlighted the importance of educators and their instructional process as a support for interest development, a point that Xu et al. (2012) also emphasized. In their study of the classrooms of exemplary African American teachers, Xu et al. noted the importance of the educators’ own interest in the subject that they teach, as well as their interest in their students as learners.

Research on interest regularly demonstrates that interest development benefits sustained engagement and performance (e.g., Crouch et al., 2018; Harackiewicz et al., 2008; Harackiewicz and Priniski, 2018), and also that interest is coordinated with and supports the development of both self-efficacy and self-regulation (e.g., Harackiewicz et al., 2008; Nuutila et al., 2020; Sansone et al., 2015). Findings also confirm that the development of interest is generally a positive process, and that even though interest may fall off because of lack of support or challenge, and can also be re-triggered (e.g., Alexander et al., 2019; Hecht et al., 2019; Renninger and Hidi, 2002).

Concluding thoughts and future study

Curiosity and interest describe two types of information search, and as such, they serve different but overlapping educational purposes. Understanding and studying their relation in practice is needed, although most studies focus only on one or the other construct. Not many of the abundant studies of curiosity have focused on classroom practice. Rather, the research conducted has primarily focused on promoting optimal levels of uncertainty, either through direct instruction to teach questioning and/or to provide experiences that involve recognizing and working with uncertainty. In promoting feelings of uncertainty, the expectation is that educators create a knowledge gap that learners want to close, and through this promote learning. However, closing a knowledge gap may negatively affect cognitive engagement and self-regulation as Clark et al. (2019b) findings suggested. Keisha's case and the Manz and Suárez (2018) study both illustrate that even when learners have generated their own uncertainty, and are provided with information intended to support them to resolve it, they are not likely to return to further think on the questions related to the uncertainty unless they are encouraged to do so.

By contrast, there are numerous studies of interest that have used instructional approaches which can be used in classrooms. These studies have pointed to a wide range of practices that educators may employ to enable learners to make meaningful connections to content. Moreover, as portrayed by both Rosa's and Dom's cases, once such connections are made, learners are then positioned to continue to seek information specific to the connections that they have been able to make, either by themselves, or along with others. Rosa and Dom benefited from continued support and opportunities to think and work with others on the content of their respective interest. Once their interest in that content began to develop, no one needed to tell them that writing was important, or to ask questions. As their case material shows, both children readily engaged in questioning; their developing interest made it rewarding to question and search for answers. The research on interest in the classroom confirms that these practices positively affect achievement, cognitive engagement, feelings of self-efficacy, and self-regulation for students of all ages, regardless of gender, race, or ethnicity (see reviews in Renninger and Hidi, 2016, 2020).

We have suggested that curiosity might be considered a particular type of trigger for interest. There are also advantages to supporting interest development that could lead to self-triggered curiosity questions. There are relatively few studies that have explicitly considered the relation between curiosity and interest development in the classroom. This situation means that there are open questions about the application of curiosity and interest in practice that need to be considered. It is recommended that future studies address how the relation between individuals' level of curiosity and interest development can be best supported. They also should consider whether the level of individuals' curiosity influences the design of curiosity-promoting activity and/or activity that promotes interest development. If so, this could suggest the need to consider whether and when it is useful to teach students to question, and/or to promote and reflect on uncertainty; it would also provide information about what type of follow-up activity, including reflection, might enable interest to be triggered and sustained.

Acknowledgments

We thank J. Melissa Running for her editorial support in preparing this chapter for publication, and gratefully acknowledge support from the Swarthmore College Faculty Research Fund.

Conceptualization and measurement of emotions in education

Conceptualization

What do we mean, from a psychological perspective, when we speak of emotions? Despite certain nuanced differences in definitions, there is a general agreement in the field about the multi-componential nature of emotions. In line with Scherer (2000); see also Scherer and Moors (2019), we describe emotions as follows: An emotion is an evaluative reaction to an important external or internal stimulus (or mental representation thereof; e.g., a fond memory) that encompasses various psychological and physical subsystems (affective, cognitive, motivational, physiological, and expressive) and serves to be able to react as quickly and flexibly as possible to a given situation.

This multi-componential conceptualization makes an emotion a more or less clear-cut psychological phenomenon. It also implies that each emotional experience is characterized by a central nervous and peripheral-physiological reaction pattern that is reflected in subjective feelings, motor reactions (especially in facial expressions, but also gestures and posture), motivational tendencies (specifically, approach vs. avoidance tendencies), and cognitions (specifically, emotion-typical thought content).

Various approaches have been proposed to order and categorize different emotions above and beyond their constituent components. Most importantly, dimensional approaches presuppose placing the variety of emotional experiences in a space of a restricted range of meaningful descriptive dimensions. Probably the most widely used dimensional model is the circumplex model of affect that classifies emotional experiences along two orthogonal dimensions, namely valence (ranging from unpleasant to pleasant) and arousal (ranging from calm to alert; see Posner et al., 2005). For example, according to this approach, both anxiety and anger would be categorized as unpleasant, highly arousing emotions. Of course, there are also other ways to categorize emotions, for example, according to their timing (i.e., whether they primarily occur before, during, or after an event) or their object focus (e.g., self- or other-related; social, topic, or outcome-related; see below).

A further conceptual aspect worth considering in the context of emotions is that they can be understood either as states—that is, momentary experiences—or traits—that is, habitual experiences (e.g., trait test anxiety; [Spielberger et al., 1976](#)). Emotional states are often very short-lived. In contrast, when considering emotions as traits, the emphasis is on the fact that individuals differ in their tendency (or disposition, susceptibility, proneness) to experience certain emotional states more readily and frequently, and/or more intensely. In line with the definition of “trait” as a core concept in personality psychology, emotional traits are supposed to be relatively stable over time. As discussed in more depth below, differentiating between emotions as states versus traits represents an important conceptual distinction for scientific inquiry into emotions, and has important implications for their measurement.

Measurement

Due to the fact that emotions are characterized by individuals’ subjective experiences, it stands to reason that they can be assessed quite simply with self-report, that is, by asking individuals about these experiences. This can take the form of open-ended questions, with individuals reporting their emotional experiences through interviews, focus groups, or video-stimulated recall methods. Alternatively, it can take the form of closed-ended Likert-type items pertaining to verbal emotion descriptions, visual stimuli, or a combination of both (see [Schutz et al., 2016](#), for a discussion of tools and approaches to gauging emotions in education). In so doing, researchers need to decide whether to assess emotions as states, by asking, for instance, “How do you feel right now?”, or as traits, by asking “How do you generally feel?”. States are often assessed via so-called “experience sampling methods” ([Larson and Csikszentmihalyi, 2014](#); see also [Goetz et al., 2016a](#)) where participants are, for example, asked to rate their emotional states at multiple, typically randomly determined instances across lessons, days, or weeks. Digital self-reports are also used to explore learners’ state emotional experiences embedded in online learning environments ([D’Mello et al., 2017](#); [Harley, 2016](#)). Traits can be assessed by asking about how one typically feels with respect to specific types of situations (e.g., mathematics tests). An alternative way of indexing trait emotions is obtaining an average across various emotional state measures with respect to a specific type of situation. This way, individuals’ relative tendency to experience a certain emotion in a particular situation is captured.

A widely-used self-report instrument for the assessment of learners’ habitual, trait-like emotional experiences in achievement contexts is the Achievement Emotions Questionnaire (AEQ) developed by Pekrun and colleagues. The measure was originally created for the use with university students ([Pekrun et al., 2011](#)) and later adapted for the use with K-12 students, and contextualized for specific school subjects (e.g., AEQ-mathematics; [Frenzel et al., 2007](#)). The AEQ is intended to assess learners’ class-related, learning-related, and test-related experiences of enjoyment, hope, pride, relief, anger, anxiety, shame, hopelessness, and boredom (sample items: “I enjoy being in class”, “I’m proud of how well I mastered the exam”, “While studying I drift off because it’s so boring”). A short version of the AEQ (i.e., four items for each scale) also exists ([Bieleke et al., 2021](#)). Additionally, drawing upon AEQ, Frenzel and colleagues developed a self-report instrument to assess teachers’ habitual experiences of enjoyment, anger, and anxiety during teaching (Teacher Emotions Scales, TES; [Frenzel et al., 2016](#)) with four items per emotion scale (sample items: “I enjoy teaching”, “I often have reasons to get angry when I teach”, “I am often worried that my teaching isn’t going so well”).

Although self-report approaches have face validity and allow for an efficient measurement of emotions, they also entail possible problems because they are prone to conscious and non-conscious biases. For example, a teacher may not want to admit that they are highly excited or agitated during teaching, or students might exaggerate their test anxiety hoping this can result in lenient grading ([Pekrun, 2020](#); [Pekrun and Bühner, 2014](#)). In order to mitigate these potential biases, objective methods of assessing emotions have been developed that are meant to bypass participants’ subjective responses. This might be achieved through qualitative methods of observation or in-depth ethnographic inquiry methods ([Schutz et al., 2016](#)). One can also make use of the expressive component of emotions by coding and quantifying typical emotion-related facial expressions ([Ekman et al., 2002](#)), which can be executed through artificial intelligence-based facial feature recognition (see e.g., [Frenzel et al., 2019](#)). Additionally, one can assess physiological processes associated with emotional experiences. These assessment approaches used to be solely lab-based, but recent technology in the form of so-called “wearables” allows for tracking a number of peripheral-physiological measures including skin-conductance, heart rate, or blood pressure, as individuals engage in certain tasks in educational settings (including classrooms; see e.g., [Donker et al., 2018](#)). Additionally, cortisol found in saliva has been used by researchers as an indicator of increased emotional arousal, and considered in the context of research on fear or stress, including test anxiety ([Mattarella-Micke et al., 2011](#)). Finally, scholars have also employed functional magnetic resonance imaging (fMRI) and electroencephalography (EEG; see e.g., [Dikker et al., 2017](#)) to examine brain-based processes underlying individuals’ emotional experiences. However, with the exception of analyzing facial expressions, self-report still constitutes the only suitable approach for assessing specific emotions (e.g., anxiety, anger, surprise) rather than valence or arousal more broadly, especially in instructional settings (see [Roos et al., 2021](#)).

Emotions in education

Short history of emotions in education

Existing research into emotions in education dates back to inaugural studies on test anxiety, conducted in the 1930s (e.g., [Brown, 1938](#)). Throughout the 20th century, research that focused on achievement emotions was largely restricted to anxiety, and test anxiety continued to be by far the most prominent construct in research on emotions in education. Test anxiety has attracted

researchers' attention since Mandler and Sarason (1952) proposed their habit interference model of anxiety and learning. Empirical evidence has confirmed the importance of anxiety for understanding human performance (Hembree, 1988; Zeidner, 1998; Richardson et al., 2012). Since the late 1960s, attributional research has broadened the perspective by considering cognitive antecedents of different emotions following success and failure, such as pride, gratitude, shame, guilt, and anger (Weiner, 1985). Researchers have further expanded the scope of inquiry during the past 20 years by exploring a broad range of achievement emotions, including, for example, enjoyment, hope, surprise, anger, boredom, disappointment, and hopelessness (Pekrun, 2006, 2018; Pekrun and Linnenbrink-Garcia, 2014; Pekrun et al., 2017b). In addition to the increasing number of different emotions that are being examined in education, the variety of contexts (e.g., achievement vs. non-achievement context), situations (social vs. non-social situation), and academic domains (e.g., mathematics, language domain), in which these emotions are being studied, has been growing exponentially during the last 20 years.

In the context of recent research on academic emotions, different groups of emotions have been identified with respect to activities, situations, and content areas to which emotions refer (i.e., their object focus). These groups include achievement emotions that are strongly related to experiences of success and failure, epistemic emotions that are caused by perceived gaps and changes in knowledge, social emotions (e.g., envy, contempt or affection for others in the classroom), as well as topic-related emotions that are directly triggered by the learning object (Pekrun et al., 2017b).

Groups of academic emotions

An overwhelming proportion of existing studies on emotions in education focuses on *achievement emotions*. Therefore, in this chapter, we pay particular attention to this group of emotions. These are emotions that occur in relation to achievement-related activities (i.e., solving a math task, or memorizing vocabulary; Camacho-Morles et al., 2021) as well as results of these activities (i.e., getting the task right, or failing to remember the correct translation), which, for students, often involve informal as well as formal achievement feedback in the form of grades or teacher comments (see Lipnevich and Smith, 2018). This feedback has been shown to elicit a range of emotions, which relate to improved or reduced motivation and performance. The ubiquity of feedback situations that inevitably elicit a wide variety of achievement emotions in students has become the focus of attention of researchers (Goetz et al., 2018; Lipnevich and Smith, 2009). Interestingly, links between specific emotions and feedback are not straightforward, and are often counter-intuitive. Specifically, positive emotions resulting from praise may tend to result in decreased motivation to invest further effort in a task (e.g., Brummelman, 2020; Lipnevich and Smith, 2009), whereas negative emotions resulting from low grades may enhance student motivation (Lipnevich et al., 2021; Turner and Schallert, 2001). Key examples of achievement emotions in relation to past achievement outcomes are pride, relief, shame, anger, and disappointment. With regard to impending achievement evaluation, anxiety, hopelessness, and hope may be experienced. Finally, joy, frustration, or boredom are typical achievement emotions that are related to achievement activities themselves (e.g., studying, completing in-class activities).

Epistemic emotions have recently started to play a major role in research (Muis et al., 2018; Pekrun and Stephens, 2012). The term "epistemic" is derived from ancient Greek and denotes thoughts and activities that aim to expand human knowledge, as exemplified by the pioneering thinking of the Greek philosophers. Thinking, however, is not just based on pure cognitive reasoning alone ("cold cognition"). Rather, it is closely tied to emotions such as surprise, curiosity, or confusion, which relate to the knowledge-generating qualities of cognitive tasks and drive the exploratory activities that are needed to expand knowledge. For these emotions, knowledge and the generation of knowledge are the objects of emotions (Pekrun, 2021a). A prototypical situation for the arousal of epistemic emotions is discrepant information and cognitive incongruity, which implies that different pieces of information are not compatible and do not fit together. A typical sequence of epistemic emotions induced by cognitive incongruity may involve (1) surprise; (2) curiosity and situational interest if the surprise is not resolved; (3) confusion when the incongruity cannot be resolved; (4) anxiety in case of severe incongruity and information that deeply disturbs existing beliefs; (5) enjoyment and delight experienced when the incongruity gets solved; or (6) frustration when solving the incongruity seems impossible.

There is also an increasing interest in *social emotions* and how they manifest in educational contexts (e.g., Immordino-Yang, 2010), although this area is less explored compared with work on achievement emotions and epistemic emotions. Learning is situated in social contexts. Even when studying alone, students never find themselves in a social vacuum; rather, the goals, contents, and outcomes of learning are socially constructed. By implication, academic settings induce a multitude of social emotions that include both social achievement emotions (such as admiration, envy, contempt, or empathy related to the success and failure of others) and non-achievement social emotions (such as love or hate in relationships with classmates and teachers). Similarly, teachers' professional activities are social in nature. Classroom teaching, interacting with colleagues, and giving advice to parents elicits a range of social emotions. Even if other people are not physically present, for example, during lesson preparation or marking exams at home, social emotions may still be prominent (e.g., getting angry at administrators for requiring detailed lesson plans).

Finally, there is the group of *topic emotions*, that is, emotions that are triggered by the contents of a learning task (Pekrun and Linnenbrink-Garcia, 2022). This group of emotions seems to be the least researched. Examples are empathic emotions pertaining to a protagonist's fate when reading a novel, emotions triggered by political events discussed during politics lessons, or emotions related to topics in science class, such as students' anxiety when told about predictions of rising temperatures related to global climate change. In contrast to achievement and epistemic emotions, topic emotions do not directly pertain to learning and problem solving, and are much narrower and more task-specific.

Origins of emotions

General approaches to the origins of emotions

Why do we experience emotions in the first place? How are emotions triggered? According to a biological perspective that considers basic physiological processes of emotions from the standpoint of the phylogenetic development of humans, emotions offer a survival advantage by preparing the organism to act adaptively. In contrast to instincts which imply highly automatic stimulus-response couplings, emotions provide the basic direction of behavior (e.g., approach or avoidance), which can then be adapted to the specific situation. Cognitive approaches to emotions focus on the extent to which cognitions (such as relevance judgments, attribution of causes of events) are involved in the genesis of emotions. Particularly influential are appraisal theories, which state that it is not situations themselves that evoke emotions, but rather, our interpretations and subjective evaluation of these situations. Finally, researchers who take a social-constructivist approach to emotions argue that they are social constructions strongly shaped by cultural and societal factors. For further reading on the origins of emotions, we encourage the reader to consult the Handbook of Emotions (Barrett et al., 2016; for further reading on appraisal theory, see Moors et al., 2013; Scherer and Moors, 2019).

Origins of emotions in the context of education

Appraisal antecedents of achievement emotions

A theory that addresses a broad range of emotions in education is Pekrun's control-value theory (CVT) of achievement emotions (Pekrun, 2006, 2018). This theory focuses primarily on achievement emotions (for a more generalized version of the CVT that also addresses social, epistemic, and other emotions, see Pekrun, 2021a). In addition to being grounded in appraisal theory, CVT integrates propositions from transactional theories of stress-related emotions (Lazarus and Folkman, 1984), attribution theory (Graham and Taylor, 2014; Weiner, 2007), and has a conceptual relation with expectancy-value theories of achievement motivation (Eccles and Wigfield, 2002; Pekrun, 1993; Wigfield and Cambria, 2010). The CVT posits that two appraisals are particularly important for the arousal of achievement emotions, namely, individuals' subjective control over learning- and performance-related activities and outcomes, and their subjective value of these activities and outcomes (see Fig. 1). Subjective control refers to one's perception of being able (or unable) to influence achievement activities and their results. Value appraisals have a categorical and a dimensional facet, in line with value concepts in other disciplines (e.g., economics). The categorical facet pertains to judgments of achievement activities and their results as desirable (positive value) or undesirable (negative value), whereas the dimensional facet pertains to how important or personally significant the activities or achievement results are (low vs. high positive or negative value).

According to the CVT, how one feels in a given achievement situation depends on the individual's combination of current control and value appraisals. Control determines our expectation of success or failure and, consequently, whether we experience positive (i.e., pleasant) or negative (i.e., unpleasant) emotions. For example, if perceived control over an upcoming exam is high and we expect success, we will tend to experience enjoyment. If, however, perceived control over achievement outcomes is very low, we may experience hopelessness. The value appraisal determines how important success or failure is in a given situation. Control and value appraisals jointly determine the intensity of the emotional experience. That is, the higher one's perceived control over the process or the outcome of a task, and the higher their positive value, the stronger the resulting positive emotions are.

Fig. 1 The control-value theory related to the antecedents of achievement emotions: Reciprocal linkages between antecedents and emotions. Adapted from Pekrun (2006).

Conversely, from low control and high negative value, intense negative emotions will result. One exception with regard to the latter contingency is boredom, in that boredom is less pronounced when a learning task or a situation is considered important or personally relevant (Goetz et al., 2019).

Links between students' control and value appraisals, and a range of achievement emotions have long been supported by extensive empirical evidence (e.g., Forsblom et al., 2022; Pekrun and Perry, 2014; Loderer et al., 2020; Putwain et al., 2018a; Shao et al., 2020). Typically, studies addressing those links used students' self-concepts or perceived competence as proxies for control appraisals, and their beliefs about the importance of achievement, and/or the personal relevance of the material to be learned, as proxies for value appraisals, focusing on trait-level mechanisms. Studies addressing links between situation-specific judgments and state achievement emotions are relatively rare (e.g., Ahmed et al., 2010; Goetz et al., 2010, 2020). Interestingly, trait- and state-level approaches provide convergent evidence regarding the direction of relationships as proposed by the CVT (Goetz et al., 2016b), implying that emotional mechanisms operate in similar ways at both levels of analysis.

Social-cognitive antecedents of emotional appraisals

Assuming that cognitive appraisals are important antecedents of emotions, the question arises, what accounts for a situation being appraised in a certain way? In sum, appraisals reside in individuals and their personal beliefs (i.e., predispositions, biases, schemas, etc.). These personal beliefs provide a lens through which individuals perceive their environment, and thus strongly influence how they interpret a situation. The CVT's social-cognitive basis implies that the social environment, as perceived by individuals, plays an important role in shaping their control and value appraisals pertaining to a particular achievement situation. Specifically, Pekrun (2006, 2018) describes a number of environmental factors relevant for achievement emotion appraisals, including (1) facets of instruction, including cognitive quality and task demands, (2) value induction, (3) autonomy support, (4) goal structures and expectations, and (5) achievement, both actual levels and the corresponding feedback and consequences (see Fig. 1). There is extensive empirical evidence showing links between those environmental factors and students' emotions. The mediating role of control and value appraisals has also been consistently demonstrated. For example, Lazarides and Buchholz (2019) provided robust evidence on the links between facets of student-perceived instructional quality pertaining to teacher support and classroom management, and students' achievement emotions. Further, Flunger et al. (2019) provided compelling evidence from a field experiment, showing that if physics teachers taught a standardized teaching unit on heat transfer with significant autonomy support (by providing choices, rationales, and general information in a noncontrolling language) instead of using regular teacher-centered instruction, students experienced more positive achievement emotions, and fewer and less intense negative emotions. There is also consistent evidence that classroom goal structures are systematically linked to students' emotions (e.g., anger, anxiety, and shame showing positive links with performance goal structures, and boredom showing negative links with mastery goal structures; see e.g., Baudoin and Galand, 2017).

Fig. 1 summarizes the main propositions of the CVT related to antecedents of emotions. Importantly, even though this theory is rooted in appraisal theory and thus primarily proposes that environmental factors predict cognitive appraisals, which in turn predict emotional experiences, it also acknowledges that emotions are reciprocally linked to their cognitive antecedents (Goetz et al., 2021). This reasoning is reflected in the recursive arrows included in the model (Pekrun, 2006, 2018).

Relevance of emotions for learning and performance

Relevance of emotions for students

In applied, field-based educational and psychological research, emotions, motivation, behavior, and achievement outcomes are typically gauged together, often through self-reports, and often targeting specific domains, such as math or languages. There is substantial evidence demonstrating that emotions and achievement outcomes are systematically linked. Researchers have proposed that the link between achievement emotions and learning outcomes may be mediated by a range of cognitive, motivational, and self-regulatory processes (Pekrun, 2006, 2018).

Indeed, there is consistent evidence showing that negative emotions including anxiety, shame, anger, boredom, or hopelessness during learning are related to unfavorable cognitive processes that include task-irrelevant thinking, shallow learning strategies, or less sophisticated metacognitive strategies. Conversely, enjoyment of learning relates negatively to irrelevant thinking, and positively to a better task focus and more effective self-regulation of learning (see e.g., Ahmed et al., 2013; Obergrösser and Stoeger, 2020).

Research, describing links between achievement emotions and achievement motivation during learning, is also ample. For example, studies have demonstrated that positive emotions and mastery goals (specifically, mastery approach goals) were positively linked (see Huang, 2011, for a meta-analysis). Similarly, positive emotions, and enjoyment in particular, are key drivers and an inherent component of intrinsic motivation (Isen and Reeve, 2005). Conversely, negative emotions (e.g., anxiety, boredom, and anger) may focus students on consequences of their potential failure at the task or the unpleasant nature of the task, and are thus linked with less self-determined types of motivation. It is worth noting, however, that research on achievement emotions and on intrinsic versus extrinsic motivation has rarely been integrated (for exceptions, see e.g., González et al., 2012; Sutter-Brandenberger et al., 2018).

A number of studies has also explored the overall relations between achievement emotions and achievement. There is consistent evidence that these relations are generally positive for pleasant/positive emotions, and negative for unpleasant/negative emotions (for an overview, see Goetz and Hall, 2020; for meta-analytic evidence, see Camacho-Morles et al., 2021; Hembree, 1988; Loderer et al., 2020; Tze et al., 2016; Zhang et al., 2019). Recent studies examined these links by employing longitudinal designs, and their findings indicated that the observed correlations were driven by reciprocal effects between emotions and academic performance (Forsblom et al., 2022; Pekrun et al., 2017a; Putwain et al., 2018b; Putwain et al., 2022). Although there is evidence supporting contingencies of “pleasant = beneficial for performance” and “unpleasant = detrimental for performance”, these links may be considerably more nuanced. For example, Pekrun (2006, 2018) suggested a further differentiation between activating (i.e., anger, enjoyment) and deactivating achievement emotions (i.e., hopelessness and boredom), resulting in a 2-by-2 taxonomy. According to this reasoning, typically positive effects are expected for pleasant and activating emotions such as enjoyment and pride, and clear-cut negative effects are expected for negative-deactivating emotions. Effects on academic achievement are, in contrast, expected to be more variable “for both deactivating positive emotions, such as relaxation, and activating negative emotions, such as anxiety” (Pekrun, 2006, p. 326). However, for many emotions the evidence for these hypothesized emotion-achievement links is still scarce and in need of further exploration. Notable exceptions are enjoyment, anxiety, and boredom, with a substantial body of research accumulated for these emotions (Camacho-Morles et al., 2021; for confusion see D’Mello et al., 2014; for shame see Turner and Schaller, 2001). So, on average, students’ enjoyment of learning is positively correlated with their academic achievement, whereas correlations for anxiety and boredom are negative (Barroso et al., 2021; Camacho-Morles et al., 2021). Anxiety can be both beneficial and detrimental for performance; however, it remains controversial if the anxiety-performance relation follows an inverted U-shaped form for academic learning. For high levels of anxiety, negative linkages with achievement are expected (for evidence, see e.g., Sung et al., 2016).

In sum, there is compelling evidence demonstrating that emotions influence academic achievement and vice versa. In fact, emotions, cognitions, motivation, learning behaviors, and achievement mutually affect each other. More research on the complex links among these variables is needed (e.g., for links between emotions, appraisals, and achievement, see Forsblom et al., 2022).

Relevance of emotions for teachers

Historically, the focal point of research on emotions in the context of education has been on the learner. Although it has long been acknowledged that teaching is a social and highly emotional practice (D’Eon et al., 2000; Goldstein and Lake, 2000; Hargreaves, 1998; Nias, 1996), research on teachers’ emotions has been predominantly descriptive and far less systematic. Recently however, research focusing on teachers’ psychological characteristics, including their emotions, has been steadily growing. As with students’ emotions, appraisal theory has been proposed to be a meaningful framework for the study of teacher emotions (e.g., Chang, 2009; Fried et al., 2015; Tsouloupas et al., 2010). Appraisal theory is also at the heart of Frenzel and colleagues’ reciprocal model of causes and effects of teacher emotions (Frenzel, 2014; Jacob et al., 2017; see Fig. 2). In line with Butler (2007), who argued that “the school is an achievement arena not only for students but also for teachers who presumably strive to succeed at their job” (p. 242), Frenzel (2014) proposed that teachers’ appraisals concerning their successes or failures regarding their teaching goals were key to understanding the antecedents of teacher emotions. The researchers showed that those teachers who perceived themselves or their teaching as contributing to high student motivation, discipline, and high-quality teacher-student relationships also reported more enjoyment and less anxiety and anger, and that those links were also reflected when examined at the within-person level (Frenzel et al., 2020). That is, teachers’ enjoyment of teaching was higher when students performed better, were motivated and disciplined, and when they perceived they had better relationships with their students.

Further, it can be assumed that teachers’ emotions, due to their effects on motivation, decisions (e.g., choice of teaching strategy), and mental flexibility, in turn, affect their teaching. Studies revealed that teacher emotions were linked with how well teachers activated their students cognitively and motivationally, how well they succeeded in classroom management, and how well they supported their students socially and emotionally. As a result, recent findings showed that teachers’ emotions were systematically related to student outcomes (see Frenzel et al., 2021, for a review, and see Pekrun, 2021b, for discussion). Specifically, teachers’ pleasant emotions have been consistently linked with student motivation, enjoyment of learning, self-regulation, and performance (Babad, 2007; Banerjee et al., 2017; Beilock et al., 2010; Frenzel et al., 2016; Keller et al., 2016), and teachers’ unpleasant emotions have been linked with undesirable student outcomes including disruptive behavior, anxiety, and reduced performance (Aldrup et al., 2018; Arens and Morin, 2016; Chang, 2013; Klusmann et al., 2016).

In general, instructional behavior and teachers’ emotions have important effects on learners. This results in positive or negative cycles of teachers’ emotions, their teaching behavior, and student outcomes. When considering emotions, it becomes evident that educational psychological research can benefit from moving beyond seeing the teacher as the key effect-exerting factor driving student outcomes. As much as teachers affect students, the reverse is also true: Students’ individual or class-level characteristics, including their own emotional experiences, level of prior knowledge and performance, motivation, discipline, and their attitude toward the teacher, can also affect teachers and their emotional well-being (Frenzel et al., 2021; Nurmi and Kiuru, 2015).

When it comes to mutual influences between teachers’ and students’ emotions, research on social interaction has shown that people can “infect” each other emotionally (Elfenbein, 2014; Hatfield et al., 1994; Parkinson, 2011). Studies by Frenzel and colleagues (Frenzel et al., 2009, 2018) provided initial support for the transmission of enjoyment between mathematics teachers and their students. In a longitudinal study, the authors showed that emotional transmission was based on the mutual perception

Fig. 2 The reciprocal model of causes and effects of teacher emotions. Figure available at: <https://doi.org/10.6084/m9.figshare.14493789.v2>, under CC license. (<https://creativecommons.org/licenses/by/4.0/>).

of behavior in the classroom (Frenzel et al., 2018). That is, positive effects of teachers' joy on students' joy were mediated by the perceived enthusiasm of teachers, and positive effects of students' joy on teachers' joy were mediated by the perceived motivational commitment of students. Similarly, Moskowitz and Dewaele (2019) showed that there are links among students' perceptions of their language, teachers' happiness, and motivation toward learning English. Using experience sampling methods, Poon et al. (2019) showed that teachers' nervousness is associated with higher subsequent levels of nervousness and irritability among students, which, in turn, impairs students' in-class satisfaction.

As such, it is imperative to consider not only students', but also teachers' emotional experiences in the context of learning and teaching. These variables represent important psychological outcomes in their own right, but they are also linked with academically meaningful cognitive outcomes, that include instructional quality and student achievement, and they are reciprocally linked with each other.

Designing emotionally healthy learning environments

A key implication of the empirical findings and theoretical contentions presented in this chapter is that it is not enough to consider only achievement outcomes, "cool cognitions", instructional ideals, or didactic techniques when designing learning environments. Educators should also tailor instructional design toward optimizing teachers' and learners' affective outcomes as critical preconditions for personal success and well-being. Such contentions have also been supported by advocates of social-emotional learning (SEL) programs who emphasize the importance of focusing on social and emotional development of students, in addition to their cognitive development (for a meta-analytic review showing that SEL programs also positively affect student achievement, see Corcoran et al., 2018, and Murano et al., 2020; for further reading, see Weissberg et al., 2015). Below we outline some ideas on how learning environments can be optimized, taking teachers' and students' emotional experiences into account. These ideas are inspired by the literature on achievement motivation and emotions (e.g., Pekrun's CVT, 2006, 2018, 2021a), emotion regulation, and SEL. These research traditions have operated in relative isolation, but they tend to converge in their implications as to how learning environments can be emotionally optimized.

Influencing students' and teachers' emotional experiences during classroom instruction

Promoting enjoyment of learning in the classroom

As emphasized by Linnenbrink-Garcia et al. (2016), in order to optimize the emotional tone in the classroom, students' enjoyment of learning should be deliberately fostered. An effective way to promote enjoyment and interest in the instructional content is to implement personally relevant and active tasks, for example, by situating lessons in the context of real-world applications of interest to students, and by allowing them to engage with study materials across various settings (Design Principle 3 suggested by Linnenbrink-Garcia et al., 2016). It is worth noting, however, that focusing on boosting students' mood and cheerful atmosphere is not enough to promote learning. It is far more important to realize that student attention and effort is more likely to be sustained when learning is enjoyable.

Supporting students' feelings of competence, enhancing autonomy, emphasizing learning, and de-emphasizing social comparison

These are design principles suggested by Linnenbrink-Garcia et al. (2016) that are of relevance to the control component of Pekrun's CVT. Students will tend to feel more in control over their learning activities and achievement outcomes when they feel competent in those tasks. The perception of mastery can be achieved by offering well-structured, reasonably paced, and clear instruction, and by implementing optimally challenging tasks at, or just slightly above, students' current skill levels. Students' feelings of autonomy can be supported with ample opportunities for student decision-making, and minimizing the use of extrinsic awards and practices that make students feel they are being controlled (e.g., avoiding telling them where to sit, or when to speak; Reeve, 2009). The potentially controlling nature of extrinsic rewards, however, may be employed to establish an initial level of motivation, but autonomy and agency should be subsequently fostered. Additionally, fostering mastery goals and taking focus away from performance goals is another key design principle for emotionally healthy classrooms. Despite the fact that many students enjoy competition, social comparison should not be sustained. In other words, games and activities that presuppose a single winner make success a scarce resource in the classroom, and suggest that success is limited to very few individuals (see Pekrun et al., 2019). Hence, this kind of instructional arrangement is not conducive to positive emotional classroom climate.

Optimizing learners' and teachers' emotional experiences by supporting mutual feelings of relatedness

As their fifth design principle for adaptive motivation and emotion in education, Linnenbrink-Garcia et al. (2016) suggested supporting students' feelings of relatedness and belonging. This notion can be extended to teachers' emotions and motivation as well. Students report enhanced interest and reduced negative affect when the perceived quality of teacher-student relationship is high (Goetz et al., 2020; Quin, 2017; Roorda et al., 2011). Similarly, the more connected teachers feel to their students, the higher their emotional well-being is shown to be (e.g., Klassen et al., 2012; Spilt et al., 2011). Feelings of relatedness between teachers and students can be promoted by spending nondirective one-on-one time (also referred to as "banking time"; cf. Driscoll et al., 2011; Pianta and Hamre, 2001) or by enhancing perceptions of mutual similarity (Gehlbach et al., 2012). The latter intervention involved having students and teachers complete a "get-to-know-you questionnaire" at the beginning of the school year, and then providing teachers with information about preferences or attitudes they shared with half of the students in their classes (randomly selected; the other half of the students were the control group). Teachers reported improved relationships with those students for whom they had received similarity information five weeks later.

Optimizing test-taking and feedback

The design of tests and assessments, the feedback provided after testing, and the consequences of individuals' performance influence students' emotions (Pekrun, 2006). If the structure, demands, and consequences of assessments are not clear to students, test anxiety is increased due to the possibility of failure. Further, tests that demand high attention can impair performance in students who are anxious about tests, because part of their cognitive resources are already consumed by worrying about failure. Anxiety can be further increased during such tests. This may be true, for example, when creative essay writing has to be carried out in a limited period of time.

Feedback about achievement on academic tests is one of the most powerful factors in the development of achievement emotions (Goetz et al., 2018). Repeated feedback on success can strengthen students' self-confidence and cultivate self-efficacy over time and increase their positive achievement emotions, such as hope for success and pride. In contrast, repeated feedback on failure undermines self-confidence and increases negative achievement emotions, such as anxiety, shame, and hopelessness. This is especially true if feedback on failure is coupled with the message that failure is due to lack of ability as opposed to students' lack of investing time and effort. Regarding feedback on achievement, teachers can strengthen students' self-confidence and positive emotions by using the following four principles (Pekrun et al., 2017b). (a) Whenever possible, mastery standards should be used and normative standards should be avoided for evaluating achievement. (b) Repeated feedback on success rather than on failure should be used by emphasizing improvement of performance, even if improvement is small. (c) Modeling adaptive approaches to dealing with failure has a vast instructional value. It is important to make clear to students that errors and mistakes should be regarded as opportunities to learn, and that abilities are malleable (e.g., by assigning the grade "not yet" instead of "fail"; Dweck, 2010). (d) Beyond evaluative feedback about success and failure, it is critical to provide formative feedback about how students can improve their competencies and attain mastery. Detailed formative feedback, combined with positive expectancies of mastery, will strengthen students' confidence in their abilities, and will support positive affective outcomes resulting from such confidence.

Supporting and fostering adaptive emotion regulation

Even if educators put forth their very best efforts to engage themselves and their learners and create emotionally sound environments for learning and teaching, negative emotions are bound to be experienced. These are inevitable because of heterogeneity in the classroom with respect to intelligence, prior knowledge and interest, as well as with respect to emotional dispositions of teachers and students alike (e.g., habitual enjoyment, test anxiety). As such, students and teachers need to have a range of strategies for regulating learning- and teaching-related emotions. There are numerous models and approaches describing the emotion regulation of students and teachers as well as effective coping strategies that enable individuals to downregulate their negative emotions (e.g., Burić et al., 2016; Donker et al., 2020; Harley et al., 2019; Jarrell and Lajoie, 2017; Lee et al., 2016).

Emotions can be regulated by directly changing their symptoms (emotion-oriented regulation) or by changing their antecedents (competence-, situation-, and appraisal-oriented regulation; Pekrun et al., 2017b). Successful emotion regulation presupposes abilities to recognize one's emotions and to select appropriate ways of managing them. These abilities are part of an individuals' emotional competencies, which consist of abilities to recognize, make use of, and regulate one's own emotions and the emotions of other persons (e.g., Goetz and Bieg, 2016). There are several ways in which emotion regulation can be trained in the classroom. For example, teachers can model emotion regulation by first labeling, identifying, and reframing their own emotions. SEL programs can be used to help students practice these skills. An example of a very popular SEL program, which focuses on fostering emotional intelligence, is the PATHS program (Promoting Alternative Thinking Strategies; Greenberg et al., 1995; for a description of the program, see also Brackett and Rivers, 2014; Parker et al., 2009). A model for the Promotion of Emotional Intelligence in Learning and Achievement Situations (the PEILAS Model) is outlined by Goetz and Bieg (2016).

When it comes to the regulation of specific emotions, the most prominent emotion is test anxiety, reflecting the long tradition of test-anxiety research (Zeidner, 1998). Programs focused on dealing with test anxiety target specific symptoms of anxiety (e.g., relaxation training), lack of self-confidence causing anxiety (e.g., cognitive therapy), or underlying competence deficits (behavioral skills training; e.g., training to improve learning strategies). Combinations of these approaches have been shown to be most effective for many students. In sum, theoretical and empirical findings suggest that there are numerous ways to design emotionally healthy learning environments for teachers and students alike. It is important to create instructional situations and contexts in such a way that students, who typically spend a large and important part of their lives in them, would experience a preponderance of positive emotions. After all, the joy of learning will undoubtedly contribute to positive academic outcomes and students' general sense of well-being. Hence, we implore researchers to continue on their path toward better understanding of links and contingencies between emotions and other meaningful variables.

Conclusion

In this chapter, we introduced emotions as multidimensional constructs with affective, cognitive, motivational, physiological, and expressive components. Based on traditional appraisal-theoretical approaches, it can be assumed that emotions arise from individuals' subjective evaluation of activities and outcomes. In the context of learning and performance, control and value appraisals are of particular importance. This evaluation is influenced by personal beliefs, but also by external circumstances. Thus, teachers have the opportunity to shape the emotional experience of students through targeted designs of learning environments and learning tasks. Emotions impact a range of cognitive, self-regulatory, and motivational processes, and, subsequently, student performance and learning. Moreover, they are important components of individuals' subjective well-being. Therefore, promoting positive emotions and reducing negative emotions in school and out-of-school learning should also be a meaningful goal and educational outcome. However, not only the emotions of students, but also those of teachers are critical to consider. After all, it's the teachers' emotions that may affect the quality of instructional processes and contribute to teachers' subjective well-being. Ultimately, it is rewarding for teachers to work with students who are filled with joy of learning and interest in the learning content, and schooling experience is more favorable for students who interact with enthusiastic and warm teachers.

Glossary

Epistemic Of or relating to knowledge or the conditions for acquiring it

Epistemology A branch of philosophy that investigates the origin, nature, methods, and limits of human knowledge

Introduction

Epistemic cognition refers to how people think about what they know and how they know it, including ideas about the nature of knowledge and reliable methods for constructing and evaluating knowledge claims. The study of knowledge itself, epistemology, has been concerned with defining knowledge, distinguishing it from opinion and other sorts of beliefs, and characterizing processes of knowledge construction for millennia. An educational interest in people becoming competent judges of knowledge and knowledge-making processes similarly can be traced back at least to Plato. The systematic study of how individuals develop ideas about knowledge and knowing, and how those ideas influence learning and reasoning, extends only to approximately the last 50 years, from Perry's (1970) seminal study of Harvard students' development of epistemic beliefs. This created a specialization in educational psychology known as the study of personal epistemology, but there are related strands of developmental and cognitive research with clear relations to how people think about what and how they know. Consequently, epistemic cognition is best thought of as a topic of interest to scholars in many fields, rather than as a field of its own.

Strands of research related to epistemic cognition

Several sub-fields of cognitive developmental research and cognitive, educational, and social psychology have pursued various lines of research that can all be viewed as focused on or related to epistemic cognition.

The field of personal epistemology originated from Perry's (1970) study of male Harvard undergraduates and their "intellectual development" through college. Perry described a developmental stage model, with nine sequential positions grouped into four main stages, each of which included predictions about how college students would interpret all of their experiences, regardless of domain or discipline. People in the first stage of Perry's model were termed dualists, and they were posited to have an objective view of the world, believing that knowledge is factual, unchanging, and the property of experts who pass it along to others. Such views meant that dualists would not engage in critical thinking about knowledge or its sources. Through cognitive disequilibrium resulting from experiences in education and elsewhere, Perry argued that people eventually move into a multipist view, believing there are no objective standards for knowledge, making all views equally valid, a sort of radical subjectivity. Some people, if they continue to encounter experiences fostering cognitive disequilibrium, were thought to move into the relativist category, acknowledging the contingent and contextual nature of knowledge and the necessity of using one's own logic and reasoning (i.e., critical thinking) to sort knowledge propositions from other types of claims. Perry's fourth stage, commitment within relativism, largely concerns how individuals adopt particular values and identities that shape their reasoning.

Perry's work initiated a line of scholarship aimed at modeling individual's beliefs about knowledge, their variation, and their development. These models can be grouped into two classes. *Developmental models* characterize differences in epistemic cognition in terms of phases or stages, positing sequential movement from one stage to the next with concomitant changes in people's views of knowledge and knowing. *Dimensional models*, on the other hand, characterize people's views of knowledge and knowing in terms of multiple beliefs or theories, which can change independently from one another. Perry's work directly inspired a number of other developmental models of epistemic cognition (e.g., Baxter Magolda, 1992; King and Kitchener, 1994).

Kuhn et al.'s (2000) work on informal reasoning about everyday problems resulted in a model that paralleled Perry's trajectory through objective and subjective views of knowledge. Absolutists view claims as facts that describe or explain a directly knowable, certain, and objective reality. These people do not see a need to think critically beyond determining which sources are expert and which knowledge claims match reality. Multiplists deny that reality can be directly knowable and view claims as subjective opinions, thus making critical thinking irrelevant. Finally, evaluativists share multiplists' view that reality is not directly knowable but, like Perry's committed relativists, they believe that critical thinking can be used to determine which claims are more justifiable than others. One of Kuhn's major contributions to the field of epistemic cognition was to distinguish domains of value judgments (e.g., personal taste, esthetics) from truth judgments (e.g., social and natural sciences) and provide evidence that developmental levels might vary across these domains.

In a major shift in conceptualization of epistemic cognition, Schommer (1990) proposed a model that comprised multiple, somewhat independent belief dimensions on which individuals might vary. These dimensions have naïve and sophisticated poles, with the assumption that more sophisticated beliefs are associated with better performance on various learning outcomes. The dimensional model most widespread in educational psychology was proposed by Hofer and Pintrich (1997) and included four related dimensions: the simplicity of knowledge, the certainty of knowledge, the source of knowledge, and knowledge justification. Such dimensions map on to features of developmental models. For example, Kuhn's (2000) absolutist would be said to believe that knowledge is simple (rather than complex), certain, is external to the knower, and is justified by authority. A key difference between developmental and dimensional models is that the former posit that these beliefs change in a systematic way, whereas the latter posit that people might develop asynchronously across dimensions.

A feature of early models of epistemic cognition is that all assumed that any conceptions about the nature of knowledge did not develop until adolescence. Over the last few decades, developmental research has made clear that such ideas begin to develop quite early in life and continue to develop throughout life (see Sandoval et al., 2016). Research on theory of mind has shown that children develop ideas about the state of other people's thinking by the age of 2 years (Montgomery, 1992). A crucial milestone is the development of false belief: the understanding that other people can believe something different from you, even when you know it to be wrong. Such an idea requires at least a tacit concept of knowledge as something independent of a knower. Developmental research has convincingly demonstrated that from infancy children are adept at drawing causal inferences from empirical evidence. By the time children reach school age (5 years) they can explicitly evaluate their own and others' causal claims and evaluate both the means of obtaining evidence and the quality of such evidence to discriminate between competing claims (Bullock et al., 2009). These abilities appear limited primarily by the knowledge children have of the particular situations being reasoned about, although it is not entirely clear how maturational constraints may operate. Developmental research demonstrates the social nature of such thinking, as much of children's early learning about the world is derived from other, usually older, people's testimony of the world. Children's trust in what other people tell them is not blind; rather, it is based on basic evaluations of trustworthiness referring to such features as the accuracy, competence, coherence, audience reception, and benevolence of sources (Clément, 2016).

Finally, research on learning in the disciplines has been concerned with relationships between how learners think about knowledge in the discipline and their efforts to learn that discipline. This work has been especially prominent in science, both in studies of learners' conceptions of the nature of science (i.e., its epistemology) and their practices of scientific investigation. A range of work has also been conducted in mathematics, history, and more recently in literature (Depaepe et al., 2016; Elby et al., 2016; Lee et al., 2016; Vansledright and Maggioni, 2016). One feature of epistemic cognition research in the disciplines is that it has been framed within discipline-specific epistemological concerns. Sometimes these overlap with the more general conceptions from personal epistemology research; for example, the concern in science education that students understand the tentativeness of science knowledge maps onto the general dimension of certainty of knowledge. Yet, within disciplinary education, the epistemologies of the disciplines are fleshed out more deeply and specifically than is typically the case in the psychology or personal epistemology literatures. Science educators link tentativeness to the theory-laden nature of observation, while asserting that some claims are more certain than others. Historians locate uncertainty in the distance between the present and the past and the ambiguity of historical objects. In mathematics, the issue of certainty presents as whether one believes mathematical procedures are given or constructed. Disciplinary research has been strongly influenced by the conception of epistemic cognition as originally coined by Kitchener (1983), that epistemic cognition is a more specified form of metacognition. Kitchener argued that epistemic cognition is used in situations where some idea of the nature of the answer being sought and possible methods for obtaining it are necessary for successful problem solving. For instance, to evaluate a scientific theory requires some understanding of what makes such a theory credible. That is, such evaluations are discipline-specific.

The last half-century has seen research on epistemic cognition grow immensely in a number of fields. The disparate roots of research into how people generate knowledge, interpret knowledge, and think about the nature of knowledge have begun, since the turn of the millennium, to converge in some ways. Current models are explicitly informed by relevant work in the field of philosophical epistemology. Contemporary models of epistemic cognition also pay more attention to the antecedents and early forms of epistemic cognition suggested by developmental psychology. Earlier debates about the specificity or generality of epistemic beliefs have mostly given way to a recognition that epistemic cognition has contextual and disciplinary aspects that are only somewhat understood, creating a need for better explanations of both the extent and mechanisms of generalization. These trends are converging to create a broader conceptualization of epistemic cognition as a process invoked in any of a myriad of situations in which people may have need to consider how or what they know. These issues are treated in depth in the further reading suggested at the end of this chapter.

Issues in epistemic cognition research

The expansion of research on epistemic cognition has raised a number of outstanding issues in the study of epistemic cognition. They include both how scholars theorize the nature of cognition itself and the consequences for modeling epistemic cognition, and how epistemic cognition can be observed and measured.

A fundamental issue in making sense of research on epistemic cognition is making sense of the cultural turn in psychology and other social sciences during the last decades of the 20th and early decades of the 21st centuries. In psychology, the emergence of Vygotskian and other sociocultural perspectives on development have co-occurred with the emergence of social perspectives in epistemology and in science studies (Duschl, 2008). The cultural turn includes a shift from seeing cognition as a fundamentally individual activity to a fundamentally social one, and from knowledge as an individual to a fundamentally social entity. This shift has been taken up to different extents, and differences in where scholars, and even fields, see the locus of explanation of epistemic cognition on this individual-social continuum creates a tangle of empirical results and interpretations that have yet to be clarified.

The cognitive constructivism underlying Piaget's genetic epistemology (Piaget, 1972) abandons the idea that knowledge is an object in the world. Instead, "*knowledge* refers to conceptual structures that epistemic agents, given the range of present experience within their tradition of thought and language, consider *viable*" (Von Glasersfeld, 1989, p. 124). That is, while cultural traditions of thought and language may shape experience, individual epistemic agents build conceptual structures that can viably be considered knowledge. This is not to say that constructivists necessarily abandon the idea of an objective reality (see Phillips, 1995, for a discussion of variants of constructivism on this point), only that individuals construct their knowledge of reality in their minds. This view of knowledge construction as an individual achievement continues to underlie much of the psychology research pertinent to epistemic cognition. The term *personal epistemology* as a moniker for this research itself conveys the assumption that persons construct epistemologies as part of their efforts to interpret the world around them. Both the developmental and dimensional models of epistemic cognition developed from personal epistemology research maintain this cognitive constructivism as the underlying definition of knowledge. Developmental models propose progressive trajectories that vary mainly in the generality they posit for the stages along the way. Dimensional models articulate dimensions of belief and their possible influences and interactions. All of these models share an assumption that cognitive representations (i.e., knowledge and belief) are constructed by individuals, via some level of reflection on experience, and then applied to subsequent experiences.

Sociocultural theories of cognition and development derived from Vygotsky (1962, 1978) locate the individual knower within a specific cultural and historical context, thereby framing knowledge as a cultural product and knowing as a cultural activity. Models of epistemic cognition that have been influenced by sociocultural perspectives vary in where they locate knowledge and knowing. What can be called a cognitive contextualist view attempts to account for how social factors influence individual knowledge construction, including individuals' ideas about knowledge and knowing. Such models attempt to account for how environmental (i.e., social) factors and features of specific domains influence individual epistemic cognition. Some propose that general epistemic beliefs develop within the social and cultural context in which people grow up (Muis et al., 2006). Elby and Hammer (2010) suggest that participation in culturally shaped patterns of activity lead to the construction of epistemic "resources," fine-grained cognitive structures tied closely to contexts of use. These contexts of use become bound into epistemic "frames" that organize the conditional activation of epistemic resources. These models differ in their proposed mechanisms of generalization of epistemic conceptions, and the extent of such generalization, but share the notion that social factors are influences on individual cognitive construction.

A stronger social perspective on knowledge and knowing derives from situative perspectives on cognition (Engeström, 1987; Lave and Wenger, 1991), allied with the social epistemology (Fuller, 1988) view of knowledge as fundamentally a social construct and epistemology as a social phenomenon. The situative perspective takes as its base unit of analysis the individual-in-interaction, emphasizing features of interaction external to individuals and their minds. This interactional view on cognition sees knowledge as distributed among social and material resources and deployed within cultural activity. Thus, individuals' and groups' interpretations of the purpose of an activity are seen as shaping the epistemic cognition that might occur. Chinn et al.'s (2014) AIR model highlights processes of epistemic cognition as tied to the epistemic aims an individual might pursue during activity, how those aims relate to non-epistemic aims, and how the aims are related to reliable processes of knowledge development. These reliable processes are social practices developed within particular communities to solve specific epistemic problems. The situative perspective on epistemic cognition thus sees knowledge as reflected in practice—in how people accomplish activity—rather than as a mental representation of some aspect of reality that is then applied.

The divergent theoretical perspectives on knowledge and cognition generally are reflected in current models of epistemic cognition, not surprisingly. The crucial difference among these perspectives with respect to epistemic cognition research is that they theorize knowledge itself, its development, and related concepts such as belief and the role of context, rather differently. Such differences have implications for the unit of analysis in epistemic cognition research (e.g., individuals' construction of knowledge propositions vs. the interplay of cultural forms of knowledge and individuals' practice) as well as for perspectives on how epistemic cognition develops (e.g., a focus on changes in individuals' conceptions of knowledge vs. changes in a community's norms and practices and individual participation in those). Whether such differences are incommensurate is perhaps an ideological question. What is clear is that broad differences in how knowledge and knowing are theorized produce differences in how issues of contextualization and generality are addressed in research on epistemic cognition. They lead to different explanations of the nature of developmental pathways for epistemic cognition. They also, naturally, produce differences in research methods for identifying, defining, and studying phenomena of epistemic cognition.

Early models of epistemic cognition, both developmental and dimensional, that proposed epistemic beliefs as general and applied consistently across domains have fallen out of favor. The idea that epistemic cognition occurs at different levels of specificity, as well as the idea that there are discipline-specific forms of epistemic cognition, has gained substantial empirical support and more recent models attempt to account for both of these ideas (see [Sandoval et al., 2016](#)). At the same time, evidence that at least some conceptions of knowledge and knowing appear at least somewhat general has left scholars of epistemic cognition with something of a dilemma. On the one hand, mechanisms of generalization are not yet clearly articulated, leaving a conceptual gap in explaining how any individual's experiences might produce particular forms of generalized epistemic conceptions, and what the limits of such generalization might be. On the other hand, methods for empirically observing or measuring epistemic conceptions may produce specificity or generality as an unintended artifact of instrumentation. For example, a number of studies have demonstrated that students' epistemic conceptions vary by domain, and even topic. Yet, given that the measures used presume, *a priori*, the existence of a common set of dimensions or beliefs across domains, it could be argued that what has been captured within such research is not really domain- or discipline-specific epistemic cognition but merely the extent to which scores on general belief dimensions vary across domains. Consequently, both the extent to which particular aspects of epistemic cognition may be general (applied across a range of contexts) and the mechanisms by which such generalizations develop remain unclear. The variability of epistemic cognition seen in research grounded in the disciplines (science, mathematics, etc.) implies that general models of epistemic belief cannot capture important differences in the epistemic norms and practices across the disciplines. Developing models grounded within specific disciplines and comparing them may provide a path for scholars to consider the aspects of epistemic cognition that potentially generalize and how they do so.

[Sandoval et al. \(2016\)](#) review of research designs and methods in epistemic cognition revealed a number of trends concerning the assessment methods used, the contexts in which research is conducted, and the kinds of epistemic cognition under study. Psychometric problems with self-report questionnaires and similar methods of assessing epistemic cognition, coupled with the often decontextualized or inauthentic contexts in which these data are gathered, and their presumptions of domain-consistency or trait-like aspects of epistemic cognition, cast doubt on research findings from such studies. The growing acceptance that epistemic cognition is largely tacit, and that people's enactment of epistemic cognition can often be different from their expressed reconstruction of that cognition, has led an increasing number of researchers to pursue concurrent assessment methods (e.g., observations, discourse analysis, think-aloud protocols) that can be implemented in contexts where participants are asked to think about knowledge and knowing (e.g., inquiry activities, searching the Internet for information on controversial issues). Researchers' models of epistemic cognition seem to predict their choice of context, with adherents to dimensional or developmental models often investigating how people enact epistemic cognition within clinical research settings, and adherents to situative models of epistemic cognition more often using various kinds of inquiry contexts as research settings. Given the wide variety of both conceptual models and concomitant research methods, there is a clear need for research involving multiple, mixed methods of gathering data, across a variety of contexts, to understand how epistemic cognition happens and develops. It would be especially salutary if competing theories and models were tested against one another.

Emerging trends in epistemic cognition research

Two recent trends in epistemic cognition research warrant mention. One is a general expansion of contexts in which scholars are studying epistemic phenomena. There is a general acknowledgment that how one thinks about what it means to know, what counts as knowledge, and how knowledge can be evaluated is relevant to a great many contexts in everyday life, in addition to formal school environments. Consequently, scholars are exploring how epistemic cognition occurs in various out-of-school settings, including museums, after-school clubs, and even everyday family interactions in the home or on walks in nature (e.g., [Bricker and Bell, 2012](#); [Marin and Bang, 2018](#)). This work reveals how epistemic cognition is sensitive to the contexts in which people interact and learn. How people think about knowledge seems to depend highly on what sort of knowledge they see themselves as trying to produce or evaluate, and for what purposes they are doing so. Scholars therefore are exploring how non-epistemic features of situations, such as family and other social relations, influence how people reason about epistemic issues. This has led to more expansive concepts related to epistemic cognition, such as epistemic climate ([Muis and Duffy, 2013](#)) and epistemic affect ([Jaber, 2015](#)), in efforts to account for how knowledge construction and evaluation are intertwined with most aspects of human activity and interaction. This expansion of the domains considered relevant to epistemic cognition and constructs to account for it is related to the broader cultural turn in psychology and the social sciences discussed above, reflecting that "knowing" is an inherent aspect of activity. At the same time, this expansion of the scope of epistemic cognition research has rendered the boundaries of the phenomena and constructs rather fuzzy. On the one hand, there is a salutary effect on research in acknowledging that human activity is nearly always knowledge-rich in multiple ways, so that studying how it is so across a broad range of contexts is likely to help us understand more clearly how people's ideas about what and how they know develop. On the other hand, a profusion of constructs and theoretical conceptualizations makes the production of a coherent account of epistemic cognition seem distant.

A second important trend is a push, driven mainly by Indigenous scholars, to recognize that Western views of knowledge constitute only one epistemological system, one that arguably does harm to people who do not share it. Within science education, in particular, the last decade has seen increasing attention to framing epistemic features of scientific disciplines as one particular sort of epistemology, and comparing that to other ways of knowing, especially Indigenous knowledge systems of nature (Marin and Bang, 2018; Marin et al., 2017). One interest in such scholarship is how members from non-dominant groups negotiate between the epistemologies of their home communities and traditions and those of institutional settings, like school, that embody Western epistemology. Another interest is how people navigate between multiple epistemologies as they become involved in projects related to equity and justice and thus make efforts to understand knowledge systems from other cultures. This work draws more directly on feminist and other standpoint epistemologies, Indigenous epistemologies, and more. It is very clearly located within situative perspectives on knowledge and cognition, theorizing knowledge itself as a cultural construct and cultural variations in forms and functions of knowledge as central foci of research (Marin et al., 2017).

Today research on epistemic cognition is being conducted across a broad array of fields and theoretical perspectives. There is a broad movement away from efforts to assess epistemic cognition using self-report measures, increased respect for the epistemological variations among disciplines and between cultures, and an increasing reliance on more direct methods of observation of epistemic cognition in action. As cultural differences in worldviews become not just increasingly apparent but increasingly hostile to each other, there is an urgent awareness that formal schooling must help young people to become reflective about their own views of knowledge and open to and tolerant of differing views. The complex issues confronting the world now and over the coming decades require citizens who can effectively engage in complex deliberations about how to resolve them in equitable ways. Research on epistemic cognition is likely to contribute in important ways to that educational project.

Classroom conditions supportive of EF	169
Training students' EF skills	172
Conclusion	174
References	174

Executive function (EF) skills are a set of attention-regulation skills that modulate attention in the service of a goal, and they are usually measured behaviorally as three inter-related skills: cognitive flexibility, working memory, and inhibitory control (Miyake et al., 2000; Zelazo et al., 2013). Cognitive flexibility involves thinking about something in multiple ways—for example, considering someone else's perspective on a situation. Working memory refers to keeping information in mind and manipulating it in some way. You might keep the beginning of a paragraph in mind while you read the rest of it, for example. Inhibitory control involves deliberately suppressing attention (and other responses) to something (e.g., ignoring a distraction while taking a test). Respectively, these three EF skills involve using attention flexibly, maintaining attention over time, and focusing attention selectively. Although these skills can be distinguished, they typically work together when we are pursuing a goal, and they are all important for characterizing problems, reasoning (making inferences), planning, keeping goals and plans in mind, and being flexible in the face of feedback.

These EF skills are often measured using abstract, decontextualized tasks that lack a significant affective or motivational component, and as such they can be considered relatively “cool” EF skills. In contrast, more “hot” EF skills are needed in situations that people really care about because they stand to win or lose something (Zelazo and Müller, 2002; Zelazo and Carlson, 2012). These situations require us to govern the motivational tendencies to approach or to avoid a meaningful stimulus. A classic example is delay of gratification as measured by the famous “marshmallow test” (Mischel et al., 1989), in which children are told they can take a small treat now or wait for a larger one. This task requires children to avoid the impulse to take the tempting reward immediately, however compelling it may be, and instead make the prudent choice to wait for the larger delayed reward.

Both cool and hot EF skills provide a necessary foundation for learning in a classroom setting: They make it possible for children to sit still, pay attention, remember and follow rules, and manage their emotions and behavior (Zelazo et al., 2016). By enabling students to hold information in mind and flexibly adopt new perspectives, cool EF skills also allow for more fully engaged, active, and reflective forms of learning (Marcovitch et al., 2008; Zimmerman, 2008), which leads to deeper and longer lasting understanding. Indeed, children with better cool EF skills actually learn more (i.e., retain more information) from a given amount of instruction and practice than do their peers with worse cool EF skills (Benson et al., 2013). For example, children with better cool EF skills showed a larger gain in math achievement between kindergarten and first grade, especially on applied problems (Hassinger-Das et al., 2014), and children with better cool EF skills were more likely to learn new concepts when trained in biology (Grenell and Carlson, 2021; Zaitchik et al., 2014).

Whereas cool EF is more strongly associated with academic outcomes, including math and reading, poor hot EF is more strongly associated with problem behaviors in school (e.g., inattentive and overactive behavior; Brock et al., 2009; Willoughby et al., 2011). Hot EF skills are important for helping children to manage their emotions and social interactions, and problem behaviors may interfere with school success. Hot EF skills in early childhood also predict later academic outcomes, even controlling for variables such as vocabulary and maternal education. For example, children's performance on a measure of delay of gratification predicted school performance in adolescence (e.g., Mischel et al., 1989). Similar long-term predictions are found for hot EF skills. For example, children's attention span-persistence, required for attending to relevant information and persisting on a task, measured at age 4 years, not only predicted math and reading achievement at age 21 years but also predicted the odds of completing college by age 25 (McClelland et al., 2013). The predictive power of EF is often greater than that of IQ, and long-term predictions of academic success and other positive outcomes are found even after controlling for IQ and childhood SES (e.g., Duckworth and Seligman, 2005; Moffitt et al., 2011; Purpura et al., 2017; Richmond-Rakerd et al., 2021; Viterbori et al., 2015).

Although EF skills are related to many aspects of academic achievement, including reading and science (e.g., Gropen et al., 2011; Kieffer et al., 2013; Nayfeld et al., 2013; St Clair-Thompson and Gathercole, 2006), the relations between EF skills and math appear to be especially robust (e.g., Blair and Razza, 2007; Blair et al., 2015; Fuhs et al., 2014; Hassinger-Das et al., 2014; Schmitt et al., 2015; Zelazo and Carlson, 2020). Positive correlations are seen even when controlling for baseline math skills, crystallized intelligence, verbal ability, general processing speed, and family background (e.g., Blair et al., 2015; Bull et al., 2011; Espy et al., 2004; McClelland et al., 2007; Monette et al., 2011; Prager et al., 2016; Verdine et al., 2014).

Several longitudinal studies have found prospective links from EF skills in early childhood to later math abilities (Blair et al., 2015; Bull et al., 2008; Clark et al., 2010, 2013; Fuhs et al., 2014; McClelland et al., 2007; Viterbori et al., 2015; Welsh et al., 2010). Studies have also found that early EF skills are a stronger predictor of later math abilities in elementary school than is IQ

or processing speed. In fact, EF skills have been found to be even better than math instruction in predicting growth in math abilities (Ribner, 2020), and serve as a protective factor for students at risk for math learning difficulties (Ribner et al., 2017).

Good EF skills also protect children against the academic and psychosocial risks associated with poverty and disadvantage. For example, although children who are (or have been) homeless and highly mobile are, on average, more likely than other children to perform poorly in school, this does not apply to children with relatively good EF skills; homeless children with good EF skills tend to succeed in school despite being homeless, thus showing evidence of resilience (Masten et al., 2012).

Research like this suggests that EF skills may play a key role in the academic achievement gap between children from lower versus higher socioeconomic status (SES) backgrounds. On average, children from lower SES families show lower levels of educational achievement than children from higher SES families, a gap that has widened over recent decades (Reardon, 2013). This gap emerges early (it is evident in kindergarten) and grows or remains stable over time (Masten, 2013). Lower SES is reliably associated with lower EF skills, even when controlling for general cognitive ability (for a meta-analysis, see Lawson et al., 2018), and EF skills account for more of the correlation between SES and academic outcomes than do measures of IQ or language ability (Fitzpatrick et al., 2014; Lawson and Farah, 2017; Nesbitt et al., 2013). Research comparing children with better and worse EF skills (and social competence) shows a gap in reading and math that starts in kindergarten, becomes larger until second grade, and then persists at least through sixth grade (e.g., Cutuli et al., 2013; Obradovic et al., 2009; McClelland et al., 2006).

Children from lower-SES families have been found to receive less environmental support for EF skills (e.g., fewer opportunities to play games that require attention regulation; Korucu et al., 2019), and they are also more likely to be exposed to more chaos, including inconsistent schedules and the lack of family routines (e.g., Matheny et al., 1995). This can make it difficult for children to predict and anticipate sequences of events (essential for goal-directed behavior such as planning and delay of gratification), and these lifestyle factors often disrupt sleep (e.g., Koopman-Verhoeff et al., 2019) and elicit high levels of chronic and recurring stress (e.g., Lupien et al., 2009)—effects that are likely to impair EF development over time due to the toxic influence of high levels of cortisol (a stress-related hormone) on relevant brain structures (e.g., Kolb et al., 2017; Shonkoff et al., 2012). Lower SES in children and youth has been found to be related to higher cortisol (Vliegthart et al., 2016), which in turn is related to smaller regional brain volumes (Merz et al., 2019). In a cross-sectional study of 1099 typically developing individuals (3–20 years), cortical surface area partially mediated the relation between SES and cool EF skills, but not the relations between SES and vocabulary or reading (Noble et al., 2015).

Children who are at risk for difficulties with EF skills include not only children growing up in poverty and exposed to more stress (e.g., Hanson et al., 2010), but also children with a wide range of clinical conditions with childhood onset (Zelazo, 2020). Indeed, difficulties with EF skills are pervasive characteristics of atypical development, and are seen in learning difficulties and learning disorders, as well as other conditions that can interfere with classroom learning, such as ADHD and disruptive behavior problems. Atypical development of hot and/or cool EF skills is also implicated in many other conditions and appears to be a transdiagnostic indicator of psychopathology (Zelazo, 2020).

The healthy development of EF skills during childhood is influenced importantly by caregivers, including teachers, who support the acquisition of these skills in specific ways. Research suggests that the development of EF skills depends importantly on autonomy-supportive mentorship, which includes providing guidance consistent with children's current level of competence (i.e., scaffolding), encouraging children to take initiative on challenging tasks, taking children's perspectives, respecting their pace, and providing them with choices, as opposed to taking control or letting them struggle too much on their own (Whipple et al., 2011). These behaviors are believed to foster independent problem solving, agency, and intrinsic motivation, thereby increasing children's opportunities to engage in self-initiated goal-directed activities and gradually strengthen their EF skills through practice, especially when combined with appropriate environmental structure (Grolnick and Pomerantz, 2009). Importantly, the sensitive calibration of challenges to children's developing skill level (providing problems that are not too easy and not too hard) allows children to obtain more practice actually solving problems, and thereby to build their EF skills—to learn by doing.

The effects of experience on brain structure and brain function, including EF skills, are seen across the lifespan. Collectively, this research shows that the activation of specific neural pathways, repeated over time, changes those pathways, rendering them more efficient (Hebb, 1949). For example, school-age children with abacus training showed evidence of greater myelination in parts of corpus callosum as well as other fiber tracts involved in motor and visuospatial function (Hu et al., 2011). These practice-related differences in myelination were correlated with behavioral performance. Similarly, children given a brief opportunity to practice EF skills in a scaffolded, supportive context showed improvements not only in their EF skills, but also in their social understanding, and these changes were associated with predictable changes in neural function (Espinete et al., 2013).

Classroom conditions supportive of EF

Similar to the home environment, the school environment can promote the healthy development of children's and adolescents' EF skills. For instance, recent research indicates that children's working memory grows significantly more during the school year months compared to the summer months, suggesting that the school environment provides children with unique opportunities to improve and practice their EF skills (Finch, 2019). Over the last several decades, research examining different aspects of the classroom environment in relation to students' EF skills have revealed a number of classroom conditions that can influence those skills, including classroom visual displays, teacher-student relationships, classroom management behaviors, the type of instructional support, and teachers' EF skills and well-being.

The ability to focus and sustain attention to relevant information are important for learning in the classroom. Growing evidence indicates that visual features of the classroom environment, specifically wall displays, can influence students' cognitive abilities and academic outcomes. For example, kindergarteners randomly assigned to a decorated classroom (i.e., many items displayed on the wall) spent significantly more instructional time off task and performed significantly worse on the post-lesson learning assessments compared to kindergarteners assigned to a non-decorated classroom (i.e., no items displayed on the wall; [Fisher et al., 2014](#)). Moreover, time off task mediated the effect of the classroom condition on kindergarteners' learning; being in a decorated classroom led to greater time off task which in turn predicted worse performance on the learning assessments.

Subsequent studies using different study designs, learning assessments, ecological contexts, and study populations have reported similar findings, namely that too many visual displays in primary school students' surrounding environment is associated with poor learning outcomes ([Barrett et al., 2015](#); [Hanley et al., 2017](#)). The influence of visually rich environments on EF skills has also been studied more directly. Children's and adolescents' performance on measures of working memory was significantly worse when randomly assigned to a testing room with many pictures compared to one with no pictures ([Rodrigues and Pandeirada, 2018, 2019](#)).

Building rapport with students is an important aspect of teachers' job as it creates a classroom environment that is more supportive of students' academic learning and the healthy development of their EF skills. Teacher-student relationships are associated with students' adjustment to school, their classroom engagement, and their academic achievement ([Berry, 2012](#); [Berry and O'Connor, 2010](#); [Cadima et al., 2016b](#); [Kořir and Tement, 2014](#); [Rimm-Kaufman et al., 2014](#)). Teacher-student relationships characterized by high conflict (i.e., high degree of discordance, negativity, and unpredictability in the teacher-student relationship) predict worse EF skills in elementary school students ([Berry, 2012](#); [de Wilde et al., 2016](#); [McKinnon and Blair, 2019](#)), whereas teacher-student relationships characterized by high closeness (i.e., high degree of warmth, positive affection, and emotional security between the teacher and student) predicts better EF skills in both elementary and middle school students ([Cadima et al., 2016b](#); [Vandenbroucke et al., 2017](#)).

Preliminary research indicates that positive teacher-student relationships protect against the negative effects of negative parent-child relationships and cumulative risk on children's EF skills. For instance, in an experimental study examining the effect of teacher support on elementary and middle school students' working memory, researchers found that when students reported a negative relationship with their parents, hearing an emotionally supportive message from a teacher after a stress induction task led to students' performing better on a measure of working memory, whereas hearing a supportive message from their parent was associated with worse performance ([Vandenbroucke et al., 2017](#)). In a more recent study, the negative correlation between cumulative risk and working memory in kindergarten students was found to be attenuated by teacher-child closeness ([Suntheimer and Wolf, 2020](#)). Together, these findings suggest not only that teacher-student relationships promote (or hinder) the healthy development of EF skills in children and adolescents, but also that positive teacher-student relationships can serve as a protective factor for students' experiencing stress at home and in other areas of their life.

Regarding negative teacher-student relationships, the association between high conflict teacher-student relationships and low levels of students' EF skills might be due to children's maladaptive behaviors in the classroom (e.g., increased aggression and inattention problems) and elevated stress levels. For example, one study showed that children with low levels of inhibitory control prior to kindergarten entry were more likely to experience higher levels of conflict with their teacher, on average; and this relationship was partially explained by children's greater inattentive and aggressive behaviors, as reported by teachers ([Berry, 2012](#)). Further, the findings linking poor inhibitory control to higher levels of teacher-student conflict were observed at multiple time points during the elementary school years, suggesting that aggression and inattention problems may set the stage for the dynamic interplay between teacher-student conflict and children's EF development across elementary school.

Because stress is known to undermine children's EF skills (e.g., [Blair et al., 2017](#)), and conflict with teachers has been shown to increase students' physiological stress levels ([Lisonbee et al., 2008](#)), the negative association between teacher-student conflict and students' EF might also be a result of students' elevated stress levels. Although research in the context of teacher-student relationships has yet to directly examine the associations between teacher-student conflict, stress, and students' EF skills, there is some evidence that shows high conflict relationships are negatively related to children's EF skills via elevated cortisol ([Martin et al., 2017](#)).

Positive teacher-student relationships may promote students' EF skills through increased engagement and exploration. When students have positive interactions and a close relationship with their teachers, they are more likely to enjoy school ([Gest et al., 2005](#)), have higher levels of confidence ([Cui et al., 2020](#)), and feel safe in the classroom ([Ben-Gal Dahan and Mikulincer, 2020](#)), leading them to engage in more challenging activities and show greater persistence when encountering difficulties during task completion ([Kikas and Tang, 2019](#); [Roorda et al., 2017](#)). Engaging in more challenging activities may provide students with more opportunities to practice using their EF skills, and thereby to grow them.

When teachers demonstrate effective classroom management—by clarifying rules and expectations, using proactive behavior management strategies, minimizing transition time between classroom activities, and establishing consistent classroom routines—they create conditions that support students' academic outcomes and cognitive skills. Studies have shown that young children's EF skills exhibit greater growth over the school year in classrooms where teachers use effective classroom management behaviors ([Choi et al., 2016](#); [Raver et al., 2011](#); [Rimm-Kaufman et al., 2009](#)), and effective classroom management has been linked to greater academic achievement, classroom engagement, and on-task behavior in kindergarteners ([Brock et al., 2009](#); [Rimm-Kaufman et al., 2009](#)). In well-managed classrooms, it is likely that children know what to do when transitioning from one activity to another due to consistent routines and clear expectations set by their teacher; whereas in poorly managed classrooms, children may not know what to do because of unclear expectations and inconsistencies in the organization of daily activities, resulting in more

off-task and counterproductive behaviors. Thus, it is likely that well-managed classrooms provide external guidance for students to practice organizing their behavior in a goal-directed manner, which subsequently strengthens their EF skills through the internalization of regulation strategies.

In addition to effective classroom management, an autonomy-supportive teaching style has been associated with a number of positive academic outcomes in students, including higher levels of academic intrinsic motivation, greater classroom engagement and use of self-regulated learning strategies, and academic achievement (Li et al., 2021; Reyes et al., 2012; Schuitema et al., 2016; Sierens et al., 2009). Teachers who use autonomy-supportive instructional practices structure classroom activities and communicate in ways that motivate students to become engaged in their learning because it reflects the students' own personal values, preferences, interests, and goals (Patall and Zambrano, 2019). Some examples of teachers' autonomy-supportive behaviors and instructional practices include: providing choice and seeking student input in learning activities, taking students' perspectives, acknowledging and accepting students' negative affect and resistance rather than suppressing or ignoring them, providing explanatory rationales of the personal relevance of learning topics and activities, using invitational language as opposed to controlling language, offering hints when students seem stuck, encouraging and praising effort and persistence, and displaying patience (Reeve and Cheon, 2021).

Research examining the associations between teachers' autonomy-supportive behaviors and students' EF skills has yielded similar results to research relating maternal autonomy-supportive behaviors to children's EF development (e.g., Bernier et al., 2010). Teachers' use of autonomy-supportive behaviors is positively associated with students' EF skills in childhood and adolescence (Merritt et al., 2012; Piccolo et al., 2019; Schuitema et al., 2016; Sosic-Vasic et al., 2015). Autonomy-supportive teachers likely influence students' EF skills through multiple pathways, including their instructional techniques, classroom management behaviors, and relationships with their students.

Regarding instructional techniques, autonomy-supportive teachers might support students' EF skills by teaching students how to become self-regulated learners. Self-regulated learners are active agents in their learning process, meaning they control their learning by setting goals, using effective study strategies, planning and using their time wisely, organizing and prioritizing materials and information, monitoring their learning and shifting approaches as needed, and seeking feedback on their performance (Zimmerman, 2008). There is growing evidence that students' use of self-regulated learning strategies is associated with their EF skills (Davis et al., 2021; Effeney et al., 2013; Follmer and Sperling, 2016; Rutherford et al., 2018). Observational research of teachers' use of self-regulated learning strategies in the classroom showed that teachers' scaffolding of students' planning and organization behaviors and flexible thinking (i.e., teaching students how to consider different approaches, perspectives, and answers to the same question or problem and providing strategies, resources, and tools to help students with planning and organization) positively predicted students' EF skills across the school year (Bardack and Obradović, 2019).

Additionally, viewing students as active agents in their own learning and allowing students to make choices in their learning activities might also help to explain the positive correlation between an autonomy-supportive teaching style and students' EF skills. For instance, in contrast to teacher-directed activities, child-directed activities are rooted in educational philosophies (e.g., the Montessori method) that perceive children as active, rather than passive, learners (van Hout-Wolters et al., 2000). In child-directed activities, children are allowed to choose what activities to be involved in and receive less direct input from their teachers. The active nature of child-directed activities is thought to provide students with opportunities for practicing and developing their EF skills. Indeed, in one study examining classroom time use and children's EF, researchers found that children who spent more time in (child-directed) free choice activities exhibited greater gains in inhibitory control across the school year (Goble and Pianta, 2017). Similarly, kindergarteners enrolled in classrooms that spent the most time in child-directed activities (about a third of the school day) demonstrated larger gains in cognitive flexibility across the school year (Ansari and Purtell, 2017). Other research comparing EF skills between children attending Montessori schools and children attending traditional public schools revealed similar findings, namely that students attending Montessori schools perform significantly better on measures of EF compared to children attending traditional schools (Courtier et al., 2021; Denervaud et al., 2019; Lillard and Else-Quest, 2006).

The work of teachers is dynamic, requiring constant attention and awareness to the shifting needs of students and the changing demands of classroom interactions. As a result, effective teaching requires EF skills. Primary and secondary school teachers' with better EF skills are more likely to engage in exemplary classroom practices, namely cultivating positive student-teacher relationships; creating a classroom climate where students feel valued, supported, and welcomed; making their lessons engaging, accessible, and coherent for their students; and creating classroom conditions that allow students to stay focused on achieving their full potential (Hiver et al., 2021). Lastly, teachers who displayed greater EF difficulties (e.g., impulsive, distracted, and disorganized classroom behaviors) were less effective at managing their time and routines in the classroom, less likely to teach their students strategies and practices that support their planning and organizational skills, and less likely to engage in autonomy-supportive teaching practices (Bardack and Obradovic, 2019). Although more research examining the associations between teachers' EF skills and classroom practices is needed, these findings suggest that teachers' EF skills might play an important role in their use of effective classroom practices.

Teaching often involves long hours without meaningful breaks or interactions with colleagues, low pay and appreciation, overcrowded classrooms and class discipline problems, and inadequate training in classroom management (Allegretto and Mishel, 2016; Stevenson et al., 2020). Not surprisingly, these demands take a psychological toll on teachers, resulting in higher levels of

perceived stress and burnout compared to other professions (Johnson et al., 2005; Steiner and Woo, 2021). The high levels of teacher stress and burnout are concerning because they are related not only to teachers' health and well-being (Burke and Green-glass, 1996; Collie et al., 2012; Poormahmood et al., 2017; Steinhardt et al., 2011; Suleman et al., 2018), but also to teacher attrition rates (Diliberti et al., 2021; Madigan and Kim, 2021); and teacher attrition has been shown to hinder students' academic progress (Ronfeldt et al., 2013).

Teachers experiencing high levels of stress and burnout likely have a reduced capacity to engage in the work of cultivating positive relationships with their students, using effective teaching methods, and creating a supportive and inclusive classroom environment for students. Indeed, teachers who experience stress and exhaustion tend to withdraw from relationships with students and report more conflict with their students (Chang, 2009; Whitaker et al., 2015). They also report feeling less effective and confident in their teaching and in providing support for their students (Grayson and Alvarez, 2008; Hoglund et al., 2015). Findings from observational and experimental studies indicate that stress impairs teachers' ability to implement effective classroom practices (Braun et al., 2019; Larson et al., 2018; Reinke et al., 2013), resulting in more negative social-emotional and academic outcomes among students (Hoglund et al., 2015; McLean and Connor, 2015). There is even evidence showing that teacher stress is negatively related to kindergartners' EF skills (Neuenschwander et al., 2017). Thus, the findings from these studies underscore the importance of reducing teacher stress to promote classroom environments where both teachers and students can flourish.

Training students' EF skills

Given the predictive importance of EF skills, there is a strong desire to improve or train students' EF skills. Early intervention is particularly important because improvements can have cascading positive effects on a child's life (e.g., Moffitt et al., 2011). Early interventions take advantage of periods of heightened neuroplasticity (often called "sensitive periods") when certain regions of the brain are particularly sensitive to environmental influence (both promotive and adverse influences; Hutten-locher, 2009).

However, EF training isn't relegated exclusively to early childhood; rather, EF training is effective across the lifespan (e.g., Diamond and Ling, 2019). Indeed, adolescents may benefit more than younger children from specific types of EF training. For example, adolescents respond better to task-relevant feedback on EF tasks than younger children (Peters and Crone, 2017). Adolescents are also more responsive to rewards and incentives used to motivate EF training (Geier et al., 2010; Payne, 2012; Steinberg, 2008). Thus, successful EF training depends on identifying developmentally appropriate practices that leverage the neural mechanisms and the environment of the trainee.

EF training has been found to be effective, but there are questions about whether training in a specific context (or on a particular task) generalizes to untrained behaviors, also known as "far transfer." In other words, does training EF skills through a game or set of activities translate to improvements in self-regulation behavior in the classroom? The research on EF training suggests that EF skills are similar to other acquired skills (e.g., cooking), and that we improve EF skills the same way we improve our cooking skills—by practicing them (e.g., Weicker et al., 2016; Zelazo, 2015).

Similar to training other skills, training EF skills can be separated into two separate domains: training the process and training the strategy. For example, cooking processes such as knife skills are trained through repetition until they become relatively automatic procedural routines, whereas cooking strategies concern declarative knowledge regarding what techniques are required in a given situation. This might be knowing which ingredients pair well together or recognizing whether a vegetable needs to be diced, chopped, or julienned. Strategies are typically taught explicitly. Similarly, EF *processes* such as working memory capacity can be improved through repetition. Meanwhile, EF-supportive strategies, such as chunking information together to effectively extend the amount of information you can hold in working memory, or psychologically distancing yourself from a situation to improve inhibitory control (White and Carlson, 2016), are usually learned through more direct instruction. In order to effectively improve someone's cooking or EF skills, both the technique and the strategy need to be trained.

An illustration of the distinction between process and strategy can be seen in working memory training. Adaptive working memory training, where task difficulty is increased as performance improves, is associated with increases in frontal and parietal brain activity (indicating ongoing EF challenges) as well as larger improvements in working memory skills than those that result from non-adaptive training (Olesen et al., 2004). In contrast, performance following non-adaptive working memory training is associated with reductions in frontal and parietal activity, compared to activity before training (Landau et al., 2004). This pattern of results suggests that training working memory skills through repetitive practice causes these skills to become automatized. In contrast, when working memory training focuses on promoting new strategies (e.g., rehearsal, mnemonics, and chunking), then frontal and parietal brain activity remains high (Kelly and Garavan, 2005). A combination of both process and strategy training yields the greatest results (Chenault et al., 2006; Jolles and Crone, 2012).

The distinction between process and strategy can help explain why so many programs that purport to support EF skills typically find evidence for near transfer, but not far transfer, because they focus exclusively on training processes. In addition to acquiring more proficient EF skills, however, children also need to understand these skills, what they are good for, and when and how to apply them. Programs that integrate both process and strategy are particularly successful and are more likely to show evidence of far transfer (e.g., Espinet et al., 2013; Hadley et al., 2020; Pozuelos et al., 2019).

One successful method for promoting EF skills is integrating EF training into structured play activities, including video games. Although this has been studied almost exclusively in early childhood, the basic principles are the same for school-age children more generally. During play (or imaginative exploration), and in a safe, low-stakes environment, children are more likely to be motivated to practice EF skills. The structured aspect of structured play can be used by educators to train the process, by encouraging repeated practice at ever higher levels of challenge, while the social interactions in play (e.g., planning) can be used to help develop strategy. For example, an educator can set up a dramatic play scenario where children pretend to be Buckingham Palace Guards and therefore must remain very still no matter what distractions appear. By recognizing what level of support children need in this task, educators can shorten or lengthen the duration of the task in order to appropriately challenge a student's inhibitory control. When children repeatedly practice these skills at an appropriate (and increasing) level of challenge, the skills (and underlying brain networks) adapt and become stronger and more efficient. But educators can also explicitly link behaviors practiced during this play activity to other, real-world scenarios, helping children learn how to apply their newly learned skills in those scenarios. These types of structured play interactions occur in the program *Tools of the Mind* (Bodrova and Leong, 2006).

A comprehensive review of EF training programs concluded that successful programs feature adaptive challenges, are sustained for long durations (e.g., 8 weeks or year-long school curricula), involve high doses of training (e.g., 30 min or more at a time), and are spaced out over time (training occurs regularly across multiple weeks rather than rapidly in consecutive days; Diamond and Ling, 2019). Furthermore, training benefits those with lower EF skills the most, and in order to see benefits on EF, assessment should challenge the limits of children's skills (i.e., they should be relatively difficult). These conclusions apply to other skills, too. For example, one wouldn't expect a one-off cooking class in a decontextualized environment to translate to improvements in home cooking.

One way to promote strategy learning and increase the likelihood of far transfer is to include a component of meta-cognitive reflection training. Reflection is a crucial component of intentional self-regulation (Cunningham and Zelazo, 2007; Semenov et al., 2020; Zelazo, 2015) during which a mental construal of a situation or problem is considered and reconsidered. Reflection helps identify what aspects of a stimulus are important relative to the problem; it can help identify which strategies to recruit in a given problem and align those strategies in a goal directed way. Scaffolded reflection can help children succeed in EF tasks they would otherwise fail (Espinete et al., 2013).

One particularly promising method of promoting reflection in children, adolescents and adults is mindfulness. Mindfulness is a particular way of paying attention on purpose, in the present moment, and nonjudgmentally (Kabat-Zinn, 1994). During mindfulness practice, participants train their attention to focus on a particular mental object (e.g., the breath) while nonjudgmentally noting other thoughts or distractions that might arise. Focusing attention in such a way, and calmly bringing it back when it wanders, is associated with improvements in EF skills and reductions in stress in children and adults (Jha et al., 2010; Klingbeil et al., 2017; Zelazo et al., 2018; Zenner et al., 2014; Zoogman et al., 2015). It also produces increased activation in key brain regions associated with EF skills (Brefczynski-Lewis et al., 2007; Hölzel et al., 2007). Mindfulness practice also reduces the impact of emotional processes that interfere with successful EF recruitment (Semenov et al., 2020). For example, adults enrolled in a mindfulness class (versus a relaxation meditation class) showed a reduction in the extent to which negative pictures (e.g., a car crash) slowed performance on a simple cognitive task (Ortner et al., 2007). By reducing reactivity to potentially distracting emotional stimuli and also training focused attention and a sense of acceptance, mindfulness practice helps provide both the necessary processes and strategies for EF skills to develop.

Two promising contexts within which EF training is most likely to be successful are school programs and family routines. Training EF skills in the classroom, specifically integrating EF practice into structured curricular activities (e.g., *Tools of the Mind*) can increase the likelihood that improvements in EF skills will be seen in the classroom setting (Blair and Raver, 2014). The structured play activities within *Tools of the Mind* keep children motivated in their EF practice while providing them with the applied practice necessary to train EF skills. Furthermore, within the context of play, children often perform at a level above their typical ability (Vygotsky, 1967). Another program that integrates EF training along with mindfulness practice and emotion regulation is *MindUP* (Hawn Foundation, 2011). In *MindUP* classrooms, students start by learning about the science behind brain development (e.g., experience changes the brain), then engage in mindfulness practices designed to reduce stress. Next, students practice EF and emotion regulation through exercises including role play and writing. Both *Tools of the Mind* and *MindUP* have been found to produce improvements in children's EF skills on standard laboratory tasks (Diamond et al., 2007; Schonert-Reichl et al., 2015).

Another promising approach is integrating EF training into daily family routines. Family routines provide structure and predictability to a child's daily schedule, making it easier for children to engage their EF skills proactively. Furthermore, the content of routines makes EF training during routines more ecologically valid—EF skills are being used in real-world situations like getting to school on time or preparing for a family meal (for review see Semenov and Zelazo, 2019; Semenov, 2021).

Given the importance of EF skills and their capacity to be trained, there is a pressing need for more research into effective training programs, especially in childhood and adolescence. Integrating programs into schools in the form of structured play (e.g., dramatic play and challenging games) and using practices such as metacognitive reflection and mindfulness are among the most effective strategies. Similar approaches can be undertaken in at-home training programs that leverage family routines to deliver sustainable EF training; however, more research is needed to identify the best practices for parents to apply research from the lab (or the school) to the living room.

Conclusion

EF skills provide a foundation for learning and predict academic success. Hot and cool EF skills are called upon throughout the school day to solve difficult math problems, remember instructions, and manage classroom interactions. Students with better EF skills learn more from a given amount of instruction. EF skills are malleable, and they can be influenced by classroom factors, such as visual aids, and teacher behaviors, such as autonomy supportive teaching practices. Effective training of EF skills requires that these skills be continually challenged by adapting the difficulty of the exercises as the skills grow. Classroom interventions have been shown to improve students' EF skills, and an emerging body of research has started to examine the types of activities outside of school (e.g., at home) that may play a role in child EF development (e.g., Barker et al., 2014; Stucke et al., 2022). Parent autonomy support behaviors, similar to teacher autonomy support behaviors, appear to promote the development of EF skills (Distefano et al., 2018; Meuwissen and Carlson, 2019). School-family partnerships have shown to be critical for promoting other non-academic skills (e.g., social emotional learning [SEL] skills; Garbacz et al., 2015) and future research might usefully investigate intervention programs that combine school and home-based approaches.

Introduction

If the experience of teaching were a valid indicator of expertise, then everybody who went through 12 years of schooling would be an expert in teaching: Most of us have experienced many hours of teaching as students in classrooms. Of course, the experience of teaching is not identical with *practicing* teaching. The 10,000 h of practice deemed necessary to develop expertise (based on early studies on chess playing; Gobet and Charness, 2006) would need to take the form of active teaching and deliberate learning. The number is important for two other reasons. Firstly, anybody who studies to become a teacher enters teacher education equipped with a 12-year experience of being taught, which is well above 10,000 h. Secondly, many who went through K-12 assume that they know what teaching—good and bad—entails. Nobody has had anything even close to this experience before starting their working life for many other professions or vocations, such as medicine, accounting, law, plumbing, hairdressing, or even cooking.

Further, many adults and even kids have at least some experience of *doing* teaching: parents teach their children, kids teach their peers, working adults teach their work colleagues, etc. Informal, often spontaneous, teaching experiences permeate human lives (Sterelny, 2012). Thus, teaching is also a universal cultural practice rather than just a specialist area of expertise: It is widely available to everybody as a part of the culture, implicitly learned, and often accomplished independently.

As a cultural activity, teaching comes with a set of routines that are recognized by members of a culture as appropriate and accountable and which tend to be relatively stable over time. This has the consequence that one can be a “good teacher” by sticking to teaching routines that are not necessarily the best. It also restricts teachers’ space for changing their routines. Parents may become worried when their children are taught in ways that they have not experienced themselves; they may not recognize the new practice as constituting appropriate teaching.

Research on teaching and teacher expertise suggests that the image of the 21st-century teacher needs to be revised. There are at least four clear reasons. First, good teaching is not identical with the mastery of stable teaching routines. Expert teachers are adaptive experts who deliberately and continuously develop their professional knowledge and skills (Bohle Carbonell et al., 2014; Ericsson et al., 1993). Secondly, teaching is not an individual practice; instead, it is a practice accomplished by a complex activity system. This activity system comprises a range of social agents (e.g., parents, students, teachers, principals, community stakeholders) and symbolic and material resources (e.g., curriculum documents, policies, teaching and learning resources, physical and digital learning spaces), all interacting with each other on multiple levels—individual, organizational, and societal (Davis, 2008). Thirdly, the teaching profession is also changing along with societal trends: professional knowledge in teaching is becoming more specialized, intertwined with theory, requiring abilities to produce various professional knowledge products and engage in a range of professional knowledge practices. In short, teaching is an expert knowledge culture (Markauskaite and Goodyear, 2017; Nerland, 2012). Finally, like other professionals, teachers increasingly face the need to solve problems that require expertise from different domains, such as teaching students with special needs and using technological tools. Therefore, they need the expertise to work with people outside their expert knowledge culture (e.g., school counselors, technology experts, parents, future employers, and other community members). Taken together, an expert teacher needs to be highly skilled, deliberate, adaptive, capable of contributing to the advancement of professional knowledge, and relationally competent.

A typical handbook chapter on expertise would focus on the question: What makes an expert? (Reimann and Markauskaite, 2018). The question directs attention to the personal capabilities that an individual possesses. Encyclopedias agree that an expert is “a person with a high level of knowledge or skill in a field” (Merriam-Webster Thesaurus, emphasis added). In this chapter, we want to avoid this possessive person-centered framing of *teacher expertise*. Building on Stigler and Miller (2018), we prefer to speak of *teaching expertise*, thereby affording the view that expert teaching is a practice associated with a *system* that is larger than a single teacher and involves *activity*—what teachers do.

In primary and secondary classrooms, as Stigler and Miller (2018) describe, teaching can be defined as consisting of “the interactions of teachers, students, and content, in classrooms, that are intended to achieve some goal or goals for students, within a specified time (e.g., a classroom lesson), together with the planning that takes place before, and the analysis that takes place after, the lesson” (p. 433). This definition draws on Lampert’s (2003) suggestion that classroom teaching is mainly relational work among the three core elements of a lesson: (1) teacher, (2) students, and (3) content. The teacher’s primary task is to manage the relationship between students and content over an extended time. Even this core system is a complex system as it is composed of multiple actors, dynamic and emergent. It becomes even more complex when we consider all the other necessary elements: (4) learning goals, (5) lesson activities, (6) learning tools, and (7) the timing and sequencing of activities. Further, teacher work is not confined to classroom teaching alone; activities such as curriculum and lesson planning involve many other “actors” who are each their own “system”. While classroom teaching is often seen as largely individual work, it is to the extreme dependent on factors outside of the individual teacher’s control and involves activities beyond the classroom. Our review of teaching expertise in this chapter embraces this expansive, activity-oriented notion of teaching.

The rest of the chapter is structured as follows: section **Exceptional performance: from experience and routine expertise to deliberate and adaptive development of personal capabilities** focuses on what teachers bring to the activity system and how they develop expert capabilities for classroom teaching. In sections **Knowledge building: from acquisition to construction of expert knowledge** and **Collective expertise: from individual excellence to networked and relational expertise**, the focus switches from teaching as the central object of expert teacher activity to the creation of knowledge relevant for teaching. While section **Knowledge building: from acquisition to construction of expert knowledge** concentrates on the kinds of knowledge that expert teachers produce, section **Collective expertise: from individual excellence to networked and relational expertise** extends this by focusing on the relational aspects of teacher expertise. Section **The ecologies of expertise: from fragmented to integrated expertise** expands this further by reviewing some ecological qualities of expertise. The final section considers how these ideas could be brought together and discusses methodological implications.

Exceptional performance: from experience and routine expertise to deliberate and adaptive development of personal capabilities

Building on the definition of classroom teaching provided above, a teacher needs to be proficient in four categories of activities: (1) formulation of learning goals, (2) selection and implementation of instructional strategies, (3) creation of learning opportunities, and (4) assessment of student progress (Stigler and Miller, 2018). All of these require knowledge, skill, and judgment and need to be performed under more or less strict time limits. The body of knowledge necessary for proficient teaching is multidimensional, comprising content knowledge, general and curriculum-specific pedagogical knowledge, and knowledge about learners and their characteristics (Shulman, 1987).

As is the case for other domains of expertise, teaching expertise requires integrating these bodies of knowledge into a performance-oriented structure (Chi et al., 1981). The differences in knowledge, skills, and judgment between novices and experts have been the subject of by now classical expertise research, documented in seminal works (Ericsson et al., 2006, 2018). The gist of this research is that experts do not only have more knowledge, but they also have it organized differently from novices, and the routine parts of it are partially or fully automatized. That is, some of the experts’ knowledge has become *tacit*; it enables perception and action without rising to the level of conscious control (Leinhardt, 1989).

Deliberate practice: how to become an expert

Looking at teacher expertise through the lens of an activity system means that we are looking at an *activity* and *system* that are different from classroom teaching: the object of which is teachers’ learning and expertise. The adage that “practice makes perfect” is scientifically supported by the observed relation between practice time and time for a particular task (the speed by which the task is executed.) The power law of practice states that the time needed for a particular task decreases logarithmically with the number of practice trials taken. This means, the improvement of performance (measured in time needed) is fast initially but slows down over time. Most explanations for this relation build on mechanisms of automatization (Fitts and Posner, 1967) and the idea that something is slowing down the learning process. For instance, we can conceive of learning from practice by initially mastering isolated sub-skills—just the serve in tennis—and later requiring the integration of sub-skills.

Although such theories can explain how somebody becomes proficient, it does not account for expertise. Experience is not identical with expertise; it may be necessary but not sufficient to achieve top levels of performance. Somewhat counter to intuition, experts resist routines (Crawford and Brophy, 2006). This has been known for years, since Ericsson et al. (1993) published their

results on the most effective forms of training in learning to play an instrument at a top level of performance. They, drawing on their results, called these most effective forms that resist routine “deliberate practice.” Ericsson and colleagues described:

At music academies master teachers provide students with individualized instruction and help them identify goals and methods for their practice sessions between meetings—this form of solitary practice was named deliberate practice

Ericsson and Harwell (2019, p. 1).

This concept engendered a considerable amount of research, which, however, has been mostly on forms of practice other than the deliberate one (i.e., single practice guided by an expert teacher). Nevertheless, the key idea remains important: To gain expertise, one must deliberately design one’s learning environment: find the right mentor, engage in the evaluative judgment of own performance and outcomes, and create the right level of challenge. In contrast to the theories of the development of everyday (including work) skills, the deliberate learner does not aim only for automatization to minimize effort but also strives to increase the ability to control performance and refine it (Ericsson and Harwell, 2019, p. 4).

Despite its importance for developing exceptional individual expertise, deliberate practice is rarely used to develop teacher expertise in its canonical form, as introduced by Ericsson. Most of the research has been conducted in pre-service teacher education (e.g., Bronkhorst et al., 2013). For in-service teachers, an older survey study (Dunn and Shriner, 1999) found that teachers’ evaluation and planning best parallels deliberate practice activities. Stigler and Miller (2018) suggest the (originally Japanese) practice of lesson study is a promising form for teachers’ deliberate practice. With the rise of video-supported lesson studies (Goldman et al., 2014) this is increasingly becoming a reality. However, at this point in time, reflection on practice is the most frequently used form of deliberate learning by far in the teaching profession (e.g., Saylor and Johnson, 2014).

Adaptive expertise: how to stay an expert

The notion of adaptive expertise complements deliberate practice and is used to describe the continuous improvement of one’s performance, particularly in changing contexts (Bohle Carbonell et al., 2014). Introduced by Hatano and Iganaki (1986), adaptive expertise is best conceptualized in comparison to *routine expertise*: unlike routine experts, adaptive experts are able to adapt to new situations quickly and to regain a high level of proficiency after a short phase of re-orientation and learning. Research into adaptive expertise focuses on the developmental dimension of professional expertise, considering not only the individual factors but also the social and organizational environment. Adaptive expertise is conceptualized as having all of the characteristics of routine expertise and deliberate practice but going beyond those by drawing to a greater extent on meta-cognitive knowledge (Bohle Carbonell et al., 2014). Specifically, adaptive expertise is seen as richer in contextual knowledge: knowing when to apply specific methods and skills and knowing how to adapt them to changes in situations and task demands.

Research on adaptive expertise in teaching is only just emerging. Outside teaching, a recent scoping literature review of adaptive expertise that primarily focuses on health education shows that “Factors influencing development include: *predisposing factors* such as knowledge (ability to integrate knowledge and innovate), beliefs and attitudes (high motivation and humility), *enabling factors* such as skills (people skills, implementing reflection and scholarly activities), resources such as curricular enablers (providing variability of cases, allowing flexibility to generate solutions, critical appraisal of textbooks) and *reinforcing factors* such as mentor-guided feedback and constant curricular review” (Kua et al., 2021, p. 347). Studies that investigate approaches for developing adaptive expertise show the importance of exploration, discovery, and access to information needed for learning. Training with low structure leads to more flexible skills when compared with procedural instruction. For example, Bell and Kozłowski (2008) compared unguided exploration with detailed step-by-step instructions in a game simulation and found that exploration yielded higher scores in an adaptive expertise task. In the same study, Bell and Kozłowski varied how learning from errors was framed: comparing error encouragement with error avoidance. Participants in the error-encouragement condition showed marginally significant higher adaptive expertise. Hughes et al. (2013) compared the same difference in error framing, but different from Bell and Kozłowski (2008), the participants did not receive information about how their errors relate to the knowledge and skills being practiced. They reported no significant correlations between error framing and adaptive expertise. This can be explained by stipulating that to learn from errors, one must attend to the error with the mindset of learning from it and gain sufficient information from the error analysis to improve knowledge and skill.

In teaching, research shows the importance of adaptive expertise in embracing innovations. For example, a case study by Yoon et al. (2015) applied an adaptive expertise lens to a science lesson enacted by three high school biology teachers. Analyzing teachers’ flexibility, deep level of understanding, and deliberate practice, they concluded that adaptive expertise could help explain teachers’ practices during major curriculum reforms. Bowers et al. (2019) used the difference between teacher adaptive expertise and teacher routine expertise to describe differences in how five science teachers went about a lesson in an elementary class. They also concluded teachers’ enactment of new science standards was associated with the moves that characterize adaptive expertise. What is interesting in both studies from an activity system’s point of view is that adaptive expertise is set directly in relation to the central object of the teacher activity: “classroom science teaching.” That is, teachers’ adaptive expertise was studied and seen as important not during teachers’ introductory learning but directly during their teaching. The activity system’s view suggests that teachers’ enactment of new tools (e.g., moving to teach online from a face-to-face classroom) or new ways of organizing an activity (e.g., joint curriculum

planning) also could be associated with their adaptive expertise, but empirical studies exploring the role and functioning of teacher adaptive expertise are still rare.

In the next section, we take an expansive view of teacher expertise and focus on the forms of knowledge underpinning teaching expertise and expert teachers' roles in constructing this knowledge.

Knowledge building: from acquisition to construction of expert knowledge

Teacher expertise is tied to exceptional performance in classrooms and also to particular roles advancing the profession. Experienced teachers often find themselves mentoring more junior colleagues. In addition, a set of new professional roles is emerging that expert teachers increasingly are expected to take on, such as innovators (Penuel et al., 2007), researchers (Darling-Hammond and Bransford, 2005), and knowledge brokers. Expert teachers as *knowledge brokers* translate research knowledge into actionable and useable knowledge for practitioners (e.g., by reducing jargon, creating templates) and facilitate the transfer from research context into local practice context (Joram et al., 2020). This is valuable because, as Cain's (2016) recent review suggests, teachers primarily attend to research when its applications to their practice are highly evident.

Knowledge management expands on the notion of knowledge brokering by focusing on teachers being in charge of facilitating an expert knowledge culture in their school and potentially across schools by working with colleagues in the same role in other schools. *Knowledge cultures* are specific to professions, comprising "... the forms of knowledge in use, the artifacts and tools provided for professional practice, the traditions and methods of knowledge production, and the collective models for knowledge application serve to give communities an integrative power" (Nerland, 2012, p. 28) (For a more extensive discussion of the concept of epistemic cultures and knowledge cultures, see Knorr Cetina (1999) and Markauskaite and Goodyear (2017)). An expert teacher is enculturated into their profession's knowledge culture and therefore in a position to enact—to adopt, adapt and extend—the values and processes in the local context. Expert teachers also are able to enculturate other teachers into how teachers accumulate, distribute and use knowledge. They do so by shaping the processes of *how* knowledge gets created and *what kind* of knowledge gets created.

Knowledge-building processes start from and end in knowledge. Hence, it is essential to ask what kinds of knowledge get created. What is it a profession or a community or practice wants to produce that counts as knowledge? Building on Blackler's (1995) taxonomy of modes of knowledge relevant for studying professional expertise, we can distinguish between (1) knowledge that is closely tied to the individual ("embrained" and "embodied" in Blackler's words), (2) knowledge that is included in social practices and tools ("encultured" and "embedded"), and (3) knowledge that is "encoded" in symbols and signs.

In teaching, the first two forms of knowledge dominate. For example, Klette and Carlsen's (2012) review shows that research concentrates on individualistic and inter-personal forms of knowledge. They reinforce in their study that teachers (in Norway in this case) engage little with research-based—that is, encoded—knowledge, nor do they produce much of external knowledge objects—that is, they are also not occupying themselves with the encoding of knowledge. This is also supported in a review on teachers' use of informal online communities and networks, where none of the use patterns point to the co-construction of knowledge objects that would go beyond narrative accounts of personal experiences or descriptive accounts of learning activities and learning resources (Macià and García, 2016).

When we look for more normative recommendations—what kinds of knowledge should teachers use if not produce?—examples from the literature comprise: (1) shared instructional products (Morris and Hiebert, 2011), (2) theories of action (Brown and Flood, 2018), and (3) principled practical knowledge (Bereiter, 2014). These are all "public, changeable knowledge products" (Morris and Hiebert, 2011, p. 6), ordered along a dimension from instrumental to conceptual.

Morris and Hiebert (2011) ground their suggestion for *shared instructional products* in improvement science, which leads them to a pragmatic-instrumental view of useful knowledge products for teachers: they need to be created around particular learning goals, of a grain size that can guide classroom instruction, be testable and improvable, and accessible to teachers when needed. Although this view of useful knowledge is based on the assumption of direct use by practitioners, Brown and Flood (2018) demonstrate in their literature review that teachers rarely apply research knowledge directly. They experiment with adapting (rather than adopting) an intervention developed elsewhere by developing a "theory of action" for the intervention. "Theories of action represent the systematic exposition of why it is believed strategies or interventions have led or will lead, to change" (Brown and Flood, 2018, p. 144). This necessitates that teachers engage with questions of why and how an intervention works, not only to what extent it works "on average."

This brings us to the third kind of knowledge: principled, practical knowledge (PPK) has characteristics of both practical know-how and scientific theory (Bereiter, 2014). Like basic scientific theory, PPK meets standards of being explicitly encoded in symbols and signs and of having explanatory coherence. However, its primary function is not explanation or prediction but practical guidance: it is "know how" intertwined with "know why." Bereiter includes the guidance property that we find also suggested by Morris and Hiebert (2011), but he makes more explicit what makes knowledge provide guidance: It is the coherence attribute.

We argue that, at this point in time, teacher expertise is limited less by the interest and ability of individual practitioners but by a lack of a knowledge culture that advances powerful knowledge objects. Those need to go beyond the instrumental objects and include the conceptual knowledge objects. For example, the knowledge that makes modern professions, such as engineering, so powerful is "what-if" knowledge (Ylikoski and Kuorikoski, 2010): "What would happen if ... we introduced <x> into our teaching

(in this school)”? In contrast, the knowledge produced in education is overly backward-oriented, too much reliant on evidence and experience. Or more precisely: it lacks the means by which evidence can inform envisioning possible futures. The production of “what-if” and other generative kinds of knowledge are missing from teachers’ practices.

The following section will zoom in on the social processes at play when teachers produce and share knowledge.

Collective expertise: from individual excellence to networked and relational expertise

The need to adapt rapidly to unforeseen and quickly changing circumstances and solve wicked challenges that cannot be understood without considering different perspectives is seen as a key feature that characterizes contemporary professional work (Goodyear and Markauskaite, 2019). Expertise to engage in joint knowledge work, distributed among people from the same or different professional domains (e.g., school counselors, social workers, and teachers), as well as professionals and non-professionals (e.g., parents), are seen as critical in present-day society. To reflect this, some contemporary notions of expertise go beyond the instrumentalist view of what counts as expertise and how it develops, to approaches that acknowledge the context-dependent and relational character of expertise. Such conceptualizations of expertise have roots in different theoretical traditions and disciplinary fields, such as cognitive sciences (Hakkarainen et al., 2017, 2004), social psychology (Edwards, 2010, 2017; Mieg, 2012), philosophy (Boon et al., 2019; Collins and Evans, 2007) and organizational studies (Treem and Leonardi, 2016). These redefinitions of expertise come under different names, such as “networked expertise” (Hakkarainen et al., 2017), “interactional expertise” (Collins and Evans, 2007), “interdisciplinary expertise” (Boon et al., 2019) and “relational expertise” (Edwards, 2017). These approaches inevitably have their distinct features—and some scholars may even disagree with our attempt to put them into the same group—but all of them acknowledge the communicative, collectively accomplished, dynamic, and, therefore, relational nature of expertise.

It is beyond our scope to review all these approaches. To illustrate this broader perspective, we focus on two theoretical lines that have been used in education most extensively: networked expertise and relational expertise.

Networked expertise

Networked expertise is an extension of the established cognitive approaches to the social-constructivist views of knowledge creation (Hakkarainen et al., 2004, 2017). According to this perspective, networked expertise is a higher-level competence that arises within networked communities from sustained engagement in knowledge sharing, joint problem-solving, and knowledge-creation practices. Such expertise is a characteristic of collectives as it emerges from “the fine-tuning of individual competencies to specific requirements of collaborative activity” (Hakkarainen et al., 2017, p. 133). The empirical studies that take this theoretical line primarily focus on how professionals share and gain their knowledge and in other ways create and cultivate their professional networks. Most of these studies rely on the methods and tools offered by social network analysis to get insight into how professionals shape their cognitive socialization.

Tuomainen et al.’s (2012) study of special needs education teachers’ networks within and beyond their schools offers an example of this perspective. Using egocentric network interviews, they asked participants to indicate from whom they get information, ask advice, collaborate, and with whom they interact informally within and beyond their school. Their results showed that these special education teachers worked as networked experts with different teachers within their schools and across the school’s boundaries and other special education-related organizations. These teachers had central positions as collaborators, boundary brokers, and knowledge-sharing agents even if they played marginal roles in the informal networks of their schools.

Overall, studies of networked expertise usually focus on understanding what this expertise looks like within collectives and what kinds of conditions enable it to emerge. These studies conceptualize networked expertise as a generic emergent quality of a group. However, they usually say less about what kind of individual capabilities underpin this expertise, how these capabilities develop, or how exactly this expertise plays out when professionals work on specific challenges or other joint objects.

Relational expertise

Relational expertise has its roots within cultural-historical activity theory (Edwards, 2010, 2017). It primarily focuses on the processes and capacities that enable professionals from two or more different fields to work across professional practice boundaries on specific joint challenges. According to this view, relational expertise is seen as arising from two interrelated processes. Firstly, it involves working together on a joint challenge or object by recognizing what kinds of professional standpoints, motives, and resources others bring to the task. Secondly, it involves aligning one’s interpretations with the responses to the interpretations and responses of the others.

According to this view, relational expertise involves a set of personal capabilities: “Knowing how to recognize the expertise of others and to be able to make one’s own expertise explicit” (Edwards, 2017, p. 8). Such capacity is described as being “professionally multilingual, recognizing the meanings that different practices give to words and their importance in each practice” (Edwards, 2017, p. 8). These capabilities enable teachers to construct shared knowledge. This common knowledge is not a simple extension of what one knows to others, but the integration of professional motives, knowledge, and ways of doing with the motives, knowledge, and ways of doing of others. Relational expertise is, thus, primarily a transformational capability.

According to this perspective, capacities for relational expertise can be learned. For example, “giving and asking for reasons” is seen as a productive way of creating common knowledge (Derry, 2013). This perspective has been often used to examine interprofessional work and collaborations across professional and community boundaries. Studies often draw on research methods and techniques for examining sociocultural practices, such as observations of joint meaning-making activities. For example, Rai (2017) has applied this perspective to examine practices through which schools in rural India have engaged parents and the local community with their children’s education and wellbeing. His specific focus was on how schools, by giving and asking for reasons in meetings with parents and other community members, most of whom had not attended schools, were creating common knowledge about what matters for each party and aligning their responses. According to this perspective, relational expertise does not substitute for contributory specialist knowledge. Instead, it is an expertise that augments the specialist expertise in ways that enables collective work.

Some relational approaches to expertise try to look deeper at the relationship between the specialist (professional or disciplinary) capabilities and the capabilities that allow working relationally across professional or disciplinary boundaries. For example, one such approach conceptualizes interdisciplinary expertise as involving “the *cognitive* ability to connect, translate and establish links between disciplinary knowledge, as well as the *metacognitive* ability to explain and understand the role of *disciplinary perspective*—consisting of, e.g., basic concepts, theories, models, methodologies, technologies, and specific ways of measuring, reasoning and modeling in a discipline—in how knowledge is used and produced” (Boon et al., 2019, p. 668). However, the empirical work lags behind corresponding theoretical advances.

The ecologies of expertise: from fragmented to integrated expertise

Expertise increasingly attracts more diverse and expansive conceptualizations. Too inclusive accounts could be unhelpful. For example, what we see in the emergence of post-truth society or denial of climate change could be regarded as an effect of making boundaries between credible expertise and plain opinion too thin. However, narrow elitist accounts that emerged from early studies of expertise (see **Exceptional performance: from experience and routine expertise to deliberate and adaptive development of personal capabilities** section) are also unhelpful. They provide too little guidance on how high levels of performance in complex domains of human life could be achieved by a broader range of people.

In this section, we focus on three aspects that are important for education: (1) the ecological notions of individual expertise; (2) multilevel conceptualizations of expertise; and (3) multiplicity of expertise.

The ecologies of individual expertise

One of the biggest challenges is that resourceful professional practice—teaching and other professions for which we prepare students—is inseparable from embodied, enacted, and distributed performance and situated within the cultural and material settings thereof (Markauskaite and Goodyear, 2017; Reimann and Markauskaite, 2018). Expertise, once conceptualized as an individual mental phenomenon that could be neatly accounted for by the theories of cognitive architecture and skill development, now increasingly is scrutinized from other theoretical perspectives, some of which we have reviewed above (Collins, 2013; Collins and Evans, 2017; Edwards, 2010). These perspectives acknowledge that human expertise cannot be understood by examining human cognition, including higher-level metacognitive processes, in isolation from the material and social environments and embodied performance. Neither can it be understood without acknowledging that expertise has a tacit, enacted dimension (Markauskaite and Goodyear, 2014). In short, the human mind, body, culture, and the world form an ecological system in which expertise develops and comes into life.

Theories of expertise development, while they sometimes acknowledge this ecology, tend to focus on individual aspects, such as skill development (e.g., deliberate practice), metacognitive ability (e.g., adaptive expertise), or communication (e.g., relational expertise). Cognitive ecology aims to bring these diverse conceptualizations together into one ontologically coherent theoretical account (Hutchins, 2010; Nersessian, 2005). Accounts of professional learning and expertise development that draw on the ecological views are just emerging. These accounts are inevitably tailored for specific domains of expertise, such as scientific discovery (Nersessian, 2012) or professional innovation (Markauskaite and Goodyear, 2017). For example, the account of professional epistemic fluency (Markauskaite and Goodyear, 2017) focuses on the capabilities that underpin professional expertise to take knowledgeable action in solving complex professional problems in human-service professions, such as teaching or school counseling. This account draws on a grounded, ecological view of human cognition (Barsalou, 2008; Hutchins, 2010) and emphasizes that such expertise involves four main capabilities: (1) to combine and integrate *different kinds of knowledge*, such as theoretical knowledge from different disciplines, practical know-how, and just-in-time developed situated understanding; (2) to coordinate and weave *different ways of knowing*, such as theory-informed and case-based reasoning; (3) to create *epistemic tools* and assemble *epistemic environments* that support one’s own or group’s joint knowledge work; and (4) to construct *conscious and conscientious-self*, that is, to be attuned to one’s own capabilities and performance as well as of capabilities and performance of those who work together. Empirical studies of expertise and learning in the human service professions often draw on ethnographic methods. Simultaneously they employ diverse analytical techniques that offer a sharp insight into the diversity of resources that people bring to the solutions of complex tasks and actions that they take (Hutchins et al., 2013; Markauskaite et al., 2020; Nersessian, 2019).

Multilevel conceptualizations of expertise

Why do teams assembled from smart students fail (Barron, 2003)? Why can the Finnish “miracle” of a successful educational system not be explained solely by the expertise of individual teachers (Simola, 2005)? The relationship between individual expertise and expertise of collectives is one of the most critical aspects in contemporary workplaces where complex tasks are done, decisions are made by multiple people, and success relies not only on individual expert performance but on the expert performance of groups and organizations. The expertise of individuals does not guarantee collective expertise, and collective expertise might not be an outcome of star individual performances. For example, an expert teacher may struggle to engage students in deep thinking if school or system assessment regimes do not promote this; similarly, a school may not need to be composed of star teachers to achieve students’ success. An essential question for education is how to develop not only capacities that underpin solo expertise but also collective expertise.

Educational research still grapples with conceptualizing the multi-layered nature of expertise and empirically studying this phenomenon. The emerging multilevel accounts of expertise that have their roots in human ecology (Fulk, 2016; Hawley, 1986) offer some tools for exploring relationships from which collective expertise emerges. Such productive relationships include not only cooperative links—usually seen as key for collective success—but also other kinds of relationships. For example, one critical factor for the successful functioning of software developers’ forums within which expertise is shared is the presence of two types of experts: those who answer questions and those who ask them. “Question askers” are not just free riders but essential actors that allow collective expertise in such networks to emerge (Fulk, 2016).

Similarly, competition in crowdsourcing, during which the expertise of multiple unaffiliated people is mobilized for a short time to work on a particular challenge, proves to be an effective way to promote rapid learning. For example, Lakhani et al. (2013) report that an online competition for solving an immunogenetic problem that lasted two weeks and involved 600 experts resulted in 1000 times faster and more accurate solutions than the benchmark. We still know little about productive configurations for expert learning.

Multiplicity of expertises

Last but not least, expertise is usually seen as a one-dimensional construct that develops through attaining increasingly higher levels of “a mastery of knowledge in a particular domain or subject area” (Fulk, 2016, p. 253) or “an objectively measurable individual problem-solving capacity” (Hakkarainen et al., 2017, p. 133, citing Ericsson, 2009). This conceptualization, however, unhelpfully hides some productive diversity that should be taken into account when we talk about learning in domains where neither the problems can be easily fitted into a particular subject area nor knowledge to solve them can be objectively measured using conventional methods. For example, what kind of expertise do different parties bring to joint problem-solving when a school counselor, a teacher, and a parent work together to develop a special learning strategy for a child with a special learning need? Seeing all three kinds of expertise as equal—thereby placing them on one continuum—or discounting some as merely experience or competence is not helpful. The very idea of expertise, thus, needs to be more flexible and ecological to account for different kinds of expertise.

Researchers have been proposing various typologies for expertise (Collins and Evans, 2007; Mieg, 2012). For example, Collins (2013) has suggested examining the trajectories through which expertise develops by locating them along three continuums, that we introduced in the **Introduction** section: (1) degree of exposure to tacit knowledge; (2) how ubiquitous or rare the expertise is (i.e., esotericism); and (3) whether it is an individual or group accomplishment. For example, expertise gained through years of parenting is rich in tacit knowledge and it is often developed through engagement in a community with other parents. Nevertheless, such expertise is quite ubiquitous within the population. Expertise in teaching is rarer but less tacit than expertise in parenting. It will be learned through the combination of exposure to formal knowledge as well as participation in collective activities with teachers, students, and parents. Counselor’s knowledge is likely to be the rarest but least tacit and developed through engagement in a specialist community rather than in the community of teachers or parents. None of these expertises are just plain opinions, and all require time to develop. Nevertheless, each of them is learned differently.

Synthesis and methodological implications: expertise through an activity system’s lens

For many years expertise has been conceptualized primarily as a property of individuals who achieve exceptional performance levels. It has been an almost exclusive research domain of cognitive psychologists. The last 20 years have brought significant changes in the studies of expertise, acknowledging that expertise as a concept applies simultaneously to individuals and collectives (Fulk, 2016). These collectives include individuals and larger units, such as groups, organizations, and systems. Further, expertise is not only about their accumulated capital and other properties but about performance, which includes learning. Therefore, what counts as expertise is also inevitably not only a cognitive question but also a philosophical, social, and political matter, where the issues of knowledge, culture, and power come into play. What counts as an expert teacher in various accreditation standards, for example, is rarely defined by explicitly referring to research on teacher expertise. Emerging studies of expertise, therefore, increasingly come from different domains, making it sometimes hard to understand how different conceptualizations of expertise interrelate and how their findings contribute to understanding the overall phenomena.

Fig. 1 A representation of second generation CHAT: collective activity, mediational means, division of labor. After Cole and Engeström (1993).

To theorize this dependence, and to motivate the conclusion that teaching expertise should be reconceptualized not as personal property but as an activity of a system, we could build on Cultural Historical Activity Theory (CHAT) that is broadly used in education (for early work see Roth and Lee, 2007). The basic CHAT framework, depicted in Fig. 1, provides a simple conceptual tool that helps view teaching (and related activities such as learning design) as an *activity system* (for detailed description and history of CHAT see Engeström, 2001; Engeström and Pyörälä, 2021).

Taking the example of a teacher conducting a lesson in a classroom, the *subject* (actor) is the teacher, the *object* (a focal entity or desired outcome) is students' learning (i.e., a change in the relation between students and lesson content) and the *tool(s)* is whatever the teacher employs to pursue students' learning and achieve the desired outcomes. A tool can be conceptual—such as a good analogy—or material, such as a paper model or worksheet. The *community of significant others* is "... the people who share with the subject interest in and involvement with the same object" (Foot, 2014, p. 331). These are primarily other teachers and students in the classroom. Relations between the subject and the community are mediated by rules and by the division of labor. *Rules* regulate the subjects' actions (e.g., a teacher cannot leave the classroom during a lesson). The *division of labor* guides what is being done by whom and how during activity, including divisions of tasks and power among teachers and students.

In CHAT, an activity involves a human collective; it is not an individual "behavior" or "action." "Activity" refers to the organized whole engaged in a process that brings about a change to the object. This process consists typically of several steps or phases, which are constituted by the subject's and participants' actions and operations. *Actions* are conscious, goal-oriented, and facilitated by tools. *Operations* are components of actions that are automated or routinized and, hence, fully or partially unconscious. Activities rise and disappear, reacting to the needs of the subject, directed toward the objects of these needs. Hence, activities can be distinguished from each other primarily by their object.

The heuristic value of CHAT is that it suggests a holistic, relational way of thinking about human activities: A change in any of the nodes will have knock-on effects on all other nodes. For instance, a change as simple as a teacher using a new app in her class to teach fractions may change not only classroom routines (the division of labor) but may change what it means to learn/do fractions (the object).

The above example representing a single activity in a classroom obviously oversimplifies teaching. For instance, there will be more than one activity instantiated in any one lesson, such as when the teacher switches between individual and group work or needs to address a disruptive student. And teachers' work is not confined to teaching alone; activities such as lesson planning, preparation for teaching, curriculum planning with peers, and professional learning during curriculum change demand their own "systems."

Nevertheless, CHAT provides some insights into a holistic picture of the metaphorical elephant that the different approaches to (teacher) expertise explore:

- The research showing that expert performance is dependent on *deliberate practice* and partial automatization (Anderson, 1987) is reflected in the distinction between (conscious, intentional) actions and (unconscious) operations.
- *Adaptive expertise* can be modeled primarily through the sensitivity of changes in the object to changes in subjects' needs and also through flexibility in tool use and rules.
- *Knowledge-building practices* and the dependence of what counts as teaching expertise on cultural and social norms (Stigler and Miller, 2018) are reflected in the tools and rules.
- *Relational expertise* and *networking expertise* are partially reflected in divisions of labor between communities and, more generally, in the network of different activity systems.
- *The multilevel, ecological views* of expertise inevitably invite us to look at the dependencies among multiple elements and activity systems.

In addition, to help organize and synthesize findings from the multi-layered and multi-disciplinary (teaching) expertise research, CHAT also provides suggestions for how to study professional expertise development with a method for intervention in activity systems called *expansive learning* (Postholm, 2014; Sannino et al., 2016). This is only an indirect contribution, though, as it is designed as an organizational change method rather than an expertise research method (Engeström, 2011). It is a welcome contribution nevertheless, because the experimental method is largely absent in expertise research where, for obvious reasons, observational and psychometric methods are much more prevalent (e.g., Ackerman and Beier, 2018; Ericsson, 2018).

Without intervening—without experimenting—scientific explanations are difficult to develop (Woodward, 2003). However, any experimental-interventionist approach to studying the development of professional expertise has to address the complexities that come with learning in open systems such as at the workplace (Campbell et al., 2001). Not only does it mean that controlling—or even just measuring—all “factors” that could interfere with the intervention is impossible, it also means conceptually that one has to accept multi-causality: A single intervention can have multiple effects and any of the effects may be produced by one or a combination of other factors (Ragin, 2014). In consequence, the unit of analysis for interventionist research on teacher expertise is the expert teaching system, not the teacher solo. This resonates with the view of teaching and teacher development as an emergent property of complex systems such as articulated by Opfer and Pedder (2011).

A second, more specific contribution of Activity Theory to the study of complex systems by intervening builds on Vygotsky's method of *double stimulation* (Vygotsky, 1999). In modern terminology, in a double simulation intervention the subject is provided with resources new to them that might potentially be useful for solving a problem even though the subject may be able to solve the problem with familiar means. The point of a double simulation experiment is “... the study of those means and devices that the subject used to organize his behavior in concrete forms most adequate for each given task” (Vygotsky, 1999, p. 59). By providing the subject with resources rather than methods and tools in ready-made form, the analysis focusses on the creative and innovative potential of the subject, thus acknowledging that the subject may have a different—and in the case of experts likely deeper—understanding of the activity than the “experimenter.” Put differently, the focus of the analysis is method or tool appropriation rather than learning to use a method or tool (Ritella and Hakkarainen, 2012). This resource-view of change also forms the core of realist accounts of causation of human behavior (Pawson and Tilley, 1997).

Overall, studies of expertise as an activity system invite researchers to combine multiple disciplines, theoretical perspectives, and methods (Nicolini, 2009): to “zoom in” and investigate very specific aspects of teacher practice using methods that give the best insight into what is happening and why, and “zooming out” and investigate relationships, using methods that give the best insight into connections between individual aspects and emerging phenomena that we as a community call “teacher expertise.”

An overview of resilience

Despite the popularity of research into psychological resilience and the ever-growing use of the term “resilience,” there is no universal definition (Aburn et al., 2016). One definition, provided by Abiola and Udofia (2011), states that resilience is “a psychological process developed in response to intense life stressors that facilitates healthy functioning” and further points out that “resilience connotes inner strength, competence, optimism, flexibility, and the ability to cope effectively when faced with adversity” (p. 2). However, it remains uncertain what is truly meant by the term “resilience” in an academic context and there is little agreement on the terminology used by researchers to ascribe what resources and factors contribute toward resiliency. For example, social support networks (Grant and Kinman, 2012; Friborg et al., 2003) and making connections, are detailed as integral elements in building resilience. Despite the use of different terminology, all substantiate the same claim. That is, having access to healthy social support networks increases the likelihood of developing resilience. Yet, the inconsistency in definitions and terminology hinders the progression of research, knowledge and understanding of such an important construct (Turner et al., 2017). Although a variety of definitions exist for resilience, the definitions are largely re-iterating the same concept (Cassidy, 2015). That is, resilience provides an individual with an increased probability to overcome challenges and cope with stressful events, while retaining or regaining their mental health (Herman et al., 2011).

In the absence of an agreed definition, the measurement of resilience must also be evaluated. As expected, there are several resilience scales, none of which are seen as the most preferable (Windle et al., 2011). Only a handful of resilience measures have been developed specifically for use in a university setting. For instance, the Academic Resilience Scale (ARS-30), focuses on self-regulated learning and self-efficacy beliefs related to a university context (Cassidy, 2016) and its focus is linked to academic success. At a similar time, the Resilience at University (RAU) scale was developed (Turner et al., 2017), which importantly recognized resilience as a skill that could be trained or developed. However, there is still a need for a university specific resilience scale that is reliable, valid, structurally sound and acknowledges the vital role of wellbeing.

Relevance of resilience for education

An evident inconsistency in definitions, terminology and measures, has left resilience research lacking in its ability to progress toward an understanding of its importance in university students. The sheer complexity and multi-dimensional nature of resilience as a construct, warrants a deeper investigation into the qualities and resources that underpin it. The development of certain internal characteristics that influence resilience are apparent, but it is essential to recognize the external factors within the environment that aid in nurturing these characteristics. Understanding what factors must be present for resilience to be developed and maintained, is crucial when attempting to cultivate a resilient student population. It is those very factors that will aid in boosting resiliency and therefore improve the overall psychological well-being and educational success of students. Regardless of this, research has demonstrated the role resilience plays in the education and wellbeing of students.

Resilience provides students with the ability to cope and manage with the stressors that often accompany studying at university (Stallman, 2010). More specifically, resilience differentiates between students who can cope with the pressures of university life and those who struggle to cope (Pidgeon et al., 2014). A huge part of studying at university demands an adaptation to the environment. Many students come from far away and it may be their first time living away from home, without the immediate help and support from their family and friends. Resilient students are increasingly likely to adjust to the university environment (Wagnild and Young, 1993; Ahern et al., 2006) and are better able to adapt under pressure (Wang, 2009; Edwards et al., 2001). Much research has demonstrated that academic resilience is a strong predictor of academic achievement in general (Beauvais et al., 2014; Mwangi and Okatcha, 2015; Solomon, 2013) and it has been further identified as a key aspect of student engagement and persistence on tasks (Jowkar et al., 2014).

Not only does resilience convey educational advantages, it is also evident that university students who have the characteristics and resources necessary to cope with the demands of university life, have better mental health (DeRosier et al., 2013; Vago and Silbersweig, 2012; Epstein and Krasner, 2013; Carver et al., 2010). Furthermore, empirical evidence shows that resilience is a key characteristic that aids an individual to cope with psychological pressures (Waxman et al., 2003) and allows students to maintain their mental health as they have the ability to quickly recover from difficult situations (Souri and Hasanirad, 2011; Ho et al., 2010). Students who believe they have the ability to overcome challenges and bounce back from adversity, are typically more likely to report feeling happier, optimistic and more confident (McIntosh and Shaw, 2017). Similarly, resilient students have greater self-esteem, self-efficacy, life satisfaction and quality of life (Abiola and Udofia, 2011; McIntosh and Shaw, 2017). Resilient students are less likely to report feeling stressed, lonely, anxious or depressed (Felsten, 2004; McIntosh and Shaw, 2017; Abiola and Udofia, 2011), and are less likely to experience psychological distress (Klohenen et al., 1996; Pidgeon et al., 2014; Byrd et al., 2012; Storrie et al., 2010).

A short review of grit

While traditional theories in psychology advocated the importance of intelligence testing when predicting achievement and success, research surfaced later that contradicted this perspective. Indeed, research indicated that neither intelligence nor IQ were the most significant predictors of success, rather it was an individual's perseverance of effort and consistency of interests (Duckworth et al., 2007). "Grit" has been defined as expressing a passion and perseverance for pursuing long-term goals. It provides individuals with the ability to strive toward achieving their long-term goals, while persisting in the face of adversity (Duckworth, 2017). Initially articulated by Angela Duckworth in 2007, the concept of grit has expanded in terms of attracting the attention of education and psychology researchers from across the globe (Duckworth et al., 2007; Duckworth, 2017). Subsequently, investigations into the potential applications of grit began, including the usefulness of grit in predicting academic outcomes such as engagement, motivation, performance, and achievement. As a result, grit was shown to be a characteristic that was strongly associated with academic outcomes. For instance, students who expressed a passion toward their schoolwork and persevered with their studies, despite academic and social challenges, were most likely to experience academic success (Lee and Sohn, 2017).

Relevance of grit for education

Since Duckworth's early research, other researchers from across the world have investigated grit and reported several useful applications, including in an educational context. Research shows the central role of grit in determining which students will excel in their academic studies and identified grit as a significant predictor of academic achievement at all levels (Wolters and Hussain, 2014; Egalite et al., 2015; Rimmelfeld et al., 2016). Moreover, grittier students were shown to spend more time studying (Cross, 2013), exemplify increased academic motivation (Eskreis-Winkler et al., 2014) and expressed a higher sense of self-efficacy (Oriol et al., 2017). It has also been documented that "grittier students" are more likely to be engaged in their academic studies (Datu et al., 2015; Hodge et al., 2017) and are more likely to obtain higher grades (Lee and Sohn, 2017; Cross, 2013; Pate et al., 2017; Montas et al., 2021).

The retention and dropout rates of students have long been a concern for educational institutions and organizations all over the world (Brown, 2012). Grit has been shown to predict the retention of military cadets in an extensive training program (Duckworth et al., 2007; Eskreis-Winkler et al., 2014; Maddi et al., 2012) and of novice teachers in challenging education environments (Robertson-Kraft and Duckworth, 2014; Duckworth and Quinn, 2009). More importantly, research has suggested that grit can greatly impact the retention of students in schools, colleges, and universities (Bazelaïs et al., 2016; Crede et al., 2016; Eskreis-Winkler et al., 2014). The identification and awareness of long-term goals and the early identification of their course of interest, are critical for student retention (Hagedorn et al., 2001).

Recently, research has suggested that applications of grit are not confined to academic outcomes, but also extend to well-being. The student mental health crisis has become of increasing concern, especially to the United Kingdom government and we know that grit is a strong contributor toward higher well-being in university students (Vainio and Daukantaite, 2015; Sharkey and Gamwell, 2017; Kannangara et al., 2018; Salles et al., 2014; Jin and Kim, 2017; Goodman et al., 2017). Further, grittier individuals are happier (Singh and Jha, 2008), have better life satisfaction (Singh and Jha, 2008) and a greater sense of belonging (Bowman et al., 2015), with further analysis showing that emotional stability during stressful or negative life events is buffered

by higher levels of grit (Blalock et al., 2015). Higher levels of grit predict positive affect (Singh and Jha, 2008; Hill et al., 2014), a greater sense of purpose (Hill et al., 2014), better self-esteem (Weisskirch, 2016), more meaning in life (Hill et al., 2014) and enhance the likelihood of pursuing engagement and pleasure in life (Culin et al., 2014). Moreover, a negative correlation has been revealed between grit and negative affect (Singh and Jha, 2008; Datu et al., 2015), depression (Jin and Kim, 2017) and stress (Lee, 2017; Kannangara et al., 2018). So, not only does grit help to determine which students are more likely to achieve and perform to a high standard, it also has an influential effect on psychological well-being. Identifying students who present low levels of grit, enables educators to direct them to support services that provide the opportunity for personal development and growth, leading to better academic and well-being outcomes.

Investigating the construct of grit and its relationship to other factors

Kannangara (2015), first articulated a languishing thriving model for dyslexia. She commented, "... a thriving dyslexic predominantly displays characteristics such as positive acceptance toward challenges, embraces them, uses signature strengths when they come across obstacles, learns from criticisms, perseveres, withstands and finds alternative approaches when they face failures," (Kannangara, 2015, p. 3). Languishing dyslexics do the reverse. The three empirical studies we describe below, show that the languishing thriving model can also be applied to university students. In these studies, Kannangara et al. (2018) investigated the validity of grit and its relationship to resilience. The three studies involved an examination of a range of factors such as resilience, self-control, well-being and mindsets in relation to grit. High grit groups and low grit groups were also compared.

Study 1

The aim of Study 1 was to investigate the construct of grit and its relationship with other non-cognitive constructs such as self-control, well-being and perceived stress. The study was carried out at the University of Bolton with a total of 440 foundation, undergraduate and postgraduate students. There were 245 female participants and 170 males. All participants were asked to complete a series of questionnaires including, the 12-item Grit Scale (Duckworth et al., 2007), the Perceived Stress Scale (PSS) (Cohen et al., 1983), the Mental Well-being Scale (Short Warwick-Edinburgh Mental Well-being Scale), the ONS Personal Well-being items (Office for National Statistics, 2011) and the Self-Control Scale (SCS) (Tangney et al., 2004).

As there were more female participants, a randomized gender sample of 150 females was compared with 150 males. Women were found to have significantly higher grit scores, mean = 41.54, versus 39.26 for men ($p < 0.01$, effect size = 0.33). Older participants scored significantly higher than younger participants, as did postgraduate students. Grit correlated highest with self-control, $r = 0.52$, followed by mental well-being, $r = 0.38$.

Study 2

Study 2 was aimed at further examining the construct of grit and its relationship to other known predictors of success. A similar method to Study 1 was used in Study 2, including measures to investigate self-control and well-being. Additionally, resilience and mindsets were also measured to further validate the meaningfulness of grit as a construct. The construct validity of grit was investigated by comparing low grit and high grit scoring participants. A total of 340 foundation, undergraduate and postgraduate students were recruited. In addition to the measures included in Study 1, resilience was measured using the Connor-Davidson Resilience Scale (CD-RISC 10) and mindsets were measured using the Mindsets Quiz.

The second study confirmed the earlier finding of gender differences in grit with women again scoring higher 40.93, versus 38.81 ($p < 0.05$, effect size = 0.31). Similar differences were also found with age and postgraduate study, as in Study 1. Older students again had significantly higher grit scores, as did postgraduate students. A multiple regression analysis showed self-control and resilience were the best predictors of grit.

Study 3

This study was designed to examine the construct of grit and its links with success and academic outcomes, from a qualitative perspective. Using a snow-ball sampling technique, a total of 10 successful graduates from the university were interviewed. Thematic analysis was used to analyze the interview transcripts. Those invited for an interview were students who graduated with a first-class honors degree and those who scored high on the Grit Scale (scores above 4, the highest score on the Grit Scale is 5).

Three main themes were identified from the interview transcripts. These were passion and perseverance, self-control and positive mindsets. Two of the 10 students interviewed started their degrees with only limited knowledge of written and spoken English and yet ended up with first class honors degrees. The students reported numerous personal challenges over the 3-year course of their degrees, including financial problems, bereavements, childcare and health problems. One student had four surgeries over the 3 years. These successful students also had excellent time management skills. In addition, their knowledge of their personal strengths and weaknesses helped them increase their success. These students also had a growth mindset and used constructive criticism from their assignments to improve their work.

Taken together these three studies show the importance of grit for academic success. The “thriving” students embrace challenges and have a growth mindset. They demonstrate learned optimism and persistence in the face of difficulties. They used their personal strengths to get the best out of themselves. Grit shows itself in their passion and determination to achieve their goals. Finally, self-control helps them bring all of the above together, with good time management and organizational skills. These studies showed that, in addition to grit and resilience, a growth mindset, strengths use, self-control and mental well-being, were also important factors in student success (Kannangara et al., 2018). This led us to think about developing a composite measure, the Bolton Uni-Stride Scale (BUSS), as a way of capturing this group of factors which were important for students to “thrive” at university (Kannangara et al., 2020).

A critical overview of grit and resilience as independent factors

The constructs of resilience and grit are often researched and discussed interchangeably. After all, there is some overlap with their definitions and applications in educational and psychological research (Stoffel and Cain, 2018). As expected, resilience and grit are closely associated (Kannangara et al., 2018; Musso et al., 2019; Montas et al., 2021; Meyer et al., 2020). More specifically, perseverance, a key concept of grit, can predict academic resilience (Ali and Rahaman, 2012). Also, goal setting, a core component of grit, is a characteristic that strongly influences the development of resilience (McIntosh and Shaw, 2017). For instance, setting relevant and meaningful goals that are aligned with their interests develops a student’s sense of motivation and commitment, that compels them to persist in the face of adversity. Indeed, recent research posited students who score high on grit are significantly more resilient than students who score low on grit (Kannangara et al., 2018). Clearly, these constructs are related to some degree. Even Angela Duckworth herself, suggests that resilience is a component of grit (Duckworth et al., 2007; Duckworth and Quinn, 2009), and research advocates the strong interrelated nature of the two constructs.

Nonetheless, evidence has mounted to suggest that resilience does not necessarily equate to grittiness, and vice versa (Hardeman, 2016). One study directly compared grit and resilience and found a negative correlation, whereby particularly gritty individuals showed lower levels of resilience (Hardeman, 2016). Although grit and resilience are highly correlated, an individual can be resilient, while that individual may not necessarily be “gritty.” Resilience reflects an ability to bounce back after challenges and engenders a positive response to failure or adversity. On the other hand, grit is considerably more goal orientated and reflects a consistent effort toward reaching short and long-term goals, despite encountering adversities. They are undoubtedly related, as part of being “gritty” is to be resilient in the face of adversity (Perkins-Gough, 2013). After all, resilience is an important part of being “gritty,” as you would be less likely to persist with long-term goal pursuit if you gave up when you encountered challenges (Stoffel and Cain, 2018). Yet, being “gritty” also requires a consistency of interests that drives passion in an individual to stay focused for a long period of time and commit to plans to achieve long term goals, which is not necessarily a characteristic of resilience. Likewise, grit is a contributor toward resilience, but there are many personal characteristics, behavioral, societal and genetic influences, affecting an individual’s capacity to overcome stressful life events (Matthews, 2020). Similarly, grit is correlated with, but distinct from, many concepts that constitute resilience, such as coping strategies (Musso et al., 2019). Both resilience and grit play an important role for the others existence, but remain distinctly separate constructs (Meyer et al., 2020).

Beyond grit and resilience: the relevance of academic tenacity

In our earlier work, we had identified six factors as being linked to academic achievement. These were grit, resilience, strengths use, self-control, mindsets, and mental well-being. Although many researchers have examined these factors separately, we have argued that they are strongly inter-related (Kannangara et al., 2020). To measure all six constructs individually would require a lengthy survey. We therefore decided to construct a short scale, which we named the Bolton Uni-Stride Scale (BUSS), to measure what we referred to as “academic tenacity.” Items were chosen from existing scales, but re-worded. We chose items which correlated the highest with the total score on the scale of origin. The final scale had 12 items. Three were adapted from the Grit Scale (Duckworth et al., 2007), two from the Self-Control Scale (Tagney et al., 2004), two from the Warwick-Edinburgh Mental Well-Being Scale (Tennant et al., 2007), two from the Mindsets Quiz, one from the CD-RISC Resilience Scale (Connor and Davidson, 2003), and two on strengths use were generated from a review of the strengths’ literature. Kannangara et al. (2020) conducted two studies to examine the validity of the BUSS.

Study 1

The BUSS was given to 1117 1st year students at the University of Bolton. Principal Axis factoring using Varimax rotation was used to identify the least number of factors. Two Factors were obtained. Factor 1 “Tenacity” had seven items and Factor 2 “Self-Composure” had five items. The Tenacity Factor accounted for 30.51% of the total variance, while Self-Composure accounted for 14.20%. Together both factors accounted for 44.71% of the total variance in BUSS scores.

Study 2

In the second study, the BUSS was given to 340 students, who were also asked to complete the short Warwick-Edinburgh Mental Well-Being Scale, the CD-RISC 10, the Grit Scale, the Self-Control Scale and the Mind-Sets Quiz. A second Factor Analysis of scores on the BUSS, confirmed the original two factor solution found in Study 1. Test-retest reliability over a three-week period was found to be 0.70 for Tenacity and 0.77 for Self-Composure. Tenacity correlated highest with resilience, $r = 0.61$, followed by mental well-being at 0.54, and then grit at 0.46. Self-Composure correlated highest with grit at $r = 0.59$, followed by self-control at 0.55.

Both studies showed that the BUSS had good reliability and validity. However, the scale had been piloted and developed at only one English university. There was therefore a need to test the scale with different populations of university students.

International validation of the Bolton Uni-Stride Scale

As noted above the problem with the further development of the BUSS was that it had been developed solely at the University of Bolton in the North-West of England. With the encouragement of our colleague, Professor Patrick McGhee, [Kannangara et al. \(2022\)](#) conducted an international validation of the BUSS. We designed a web-based survey, which was delivered over the Prolific platform. Prolific offers access to survey participants worldwide, who are paid for completing surveys ([Palan and Schitter, 2018](#)). Prolific enables researchers to specify the samples they wish to survey. In our case we wanted to ensure that we surveyed university students, and participants who were fluent in English. We recruited a sample of 1043 individuals from across 30 different countries. The largest group of students was from the United States ($n = 399$), followed by Portugal ($n = 119$), Poland ($n = 102$) and Mexico ($n = 68$). Participants were asked to complete the following standardized questionnaires:

1. The Bolton Uni-Stride Scale ([Kannangara et al., 2020](#)).
2. The Self-Control Scale ([Tagney et al., 2004](#)).
3. The Future Work Self Scale ([Strauss et al., 2012](#)).
4. The Connor Davidson Resilience Scale, CD-RISC 10 ([Connor and Davidson, 2003](#)).
5. The 14-item version of the Warwick Edinburgh Mental Wellbeing Scale ([Tennant et al., 2007](#)).
6. The Short Grit Scale ([Duckworth and Quinn, 2009](#)).

Although participation was voluntary, respondents received a small cash payment via the Prolific website for completing the questionnaires.

A confirmatory factor analysis on the BUSS international data again confirmed the existence of a two-factor structure of the BUSS, with seven items loading on the Tenacity Factor and five on the Self-Composure Factor. Item 8, *"I set goals, but after a while I decide on a new set of goals,"* loaded only weakly onto the Self-Composure Factor. The internal consistency of the BUSS was good at 0.80, with Tenacity being 0.83 and Self-Composure, 0.57. Encouragingly Total BUSS scores correlated 0.73 with the Short Grit Scale and 0.69 with the CD-RISC Resilience Scale. Item discrimination analysis showed that all 12 BUSS items discriminated between high and low scorers on the scale. A linear regression with Tenacity as the dependent variable, showed that the most significant predictors were Grit, Resilience and Self-Control, in that order. The international validation study showed that the BUSS was a reliable and valid measure of academic tenacity with this sample of international university students.

Does academic tenacity actually matter?

To answer this question, the international sample was divided into High scorers ($n = 466$), versus Low scorers on the BUSS ($n = 492$). High scorers were defined as those individuals with scores between 41 and 57 and Low scorers those with scores between 20 and 40. [Table 1](#) clearly demonstrates that Low scorers on the BUSS, had significantly lower scores on each of the study dependent

Table 1 High versus low BUSS scorers on the study dependent variables.

Measure	High BUSS 41–57, $n = 466$	Low BUSS 20–40, $n = 492$	Value of t , p value	Effect size, Hedges' g
Self-control	38.73	28.35	$t = -18.87$, $p = 0.001$	1.22
Future work self	18.12	13.27	$t = -15.64$, $p = 0.001$	1.01
CD RISC resilience	38.50	30.99	$t = -20.74$, $p = 0.001$	1.35
Warwick Edinburgh Mental wellbeing	50.05	40.97	$t = -17.06$, $p = 0.001$	1.12
Short grit scale	28.54	22.36	$t = -21.34$, $p = 0.001$	1.37

variables. The largest effect sizes were for the Short Grit Scale and the CD-RISC 10 Resilience measure, again showing the importance of the concepts of Grit and Resilience. The Table demonstrates that Academic Tenacity, as measured by the BUSS, does actually matter. The biggest effect sizes are for grit and resilience.

Conclusion

This chapter has considered the importance of the concepts of grit and resilience, specifically for university students. Three studies conducted by the authors examined the concept of grit. Although these studies confirmed the importance of grit for academic success, they also suggested that other factors were important. The authors put forward a model of “thriving versus languishing students.” They argued that six factors were critical for thriving. In addition to grit, these were resilience, self-control, mindsets, mental well-being, and strengths use. Rather than assessing each of these attributes individually, the authors devised a scale, the BUSS, to tap into all six factors in a short 12-item scale. Two studies established a two-factor structure for the scale, “Tenacity” and “Self-Composure.” The scale possesses good internal reliability and test re-test reliability, has good face and content validity, as well as good convergent and concurrent correlational validity. This has been confirmed in an international validation. The BUSS is now being translated into different languages and is being used by other researchers.

It is of course one thing to measure the concepts of grit, resilience and tenacity, but what can be done to improve them? The Hummingbird Project (Platt et al., 2020), offered an opportunity to deliver a six-week psycho-education project based on Positive Psychology (Rashid and Seligman, 2018; Carr, 2020), to improve wellbeing, hope and tenacity in high school students. The intervention was delivered to over 1000 high school students in its 1st year and has now been running for 3 years. The researchers have also developed Hummingbird Primary and, along with the Open University, have developed a “Bounce Back” program for parents, to share positive psychology techniques with them. Additionally, there are plans to devise a similar multicomponent Positive Psychology Intervention for university students.

Introduction

The capacity of people to learn, to be educated, and to think intelligently became a focus of attention during the 19th century as nations industrialized and became more dependent upon the skills of their citizenry. National education systems emerged, and with them, decisions were needed as to who could best benefit from educational opportunities at schools and universities (Anderson, 1982). Alfred Binet's first intelligence tests were introduced in response to the French government's call for help regarding the need to identify students with intellectual disabilities in a fair and impartial manner (Binet and Simon, 1916; Fancher, 1987). Governments wanted to know who could best take advantage of higher education and could use their learning to contribute to society.

Binet and others recognized the need for impartiality in using newly-developed indices of mental ability (Devonis, 2016; Fancher, 1987), concerns that extend to the present day (Camilli, 2013; Deary, 2001). Scientists used their new intelligence measures, and the theories around them, to understand people's potential at solving problems. *Intelligence*, as used here, refers to people's capacity to problem solve. The title of this entry is "*Intelligences*", in the plural, and we take as our role explaining how experts gradually came to accept and understand the multifaceted aspects of human reasoning recognized today.

During much of the 20th and early 21st centuries, anyone hoping to discuss intelligences in the plural would need to defend their conception that intelligence was multifaceted rather than unitary. As recently as 1994, in a Wall Street Journal editorial entitled "Mainstream Science on Intelligence," Linda Gottfredson and 52 co-signers emphasized that intelligence was a single, unitary and "... very general mental capability that, among other things, involves the ability to reason, plan, solve problems, think abstractly, comprehend complex ideas, learn quickly and learn from experience" (reprinted as Gottfredson, 1997, p. 13). However, mainstream science on the nature of intelligence was shifting even as the editorial was written.

Our coverage

The debate over the existence of a single general intelligence versus multiple intelligences extends over a century of theoretical and empirical work. The approach here is to trace that debate and to explain some of the research challenges that made it so difficult to resolve. Our history begins with the section “One General Intelligence or Many ...?”, and covers the first half of the 20th century, followed by “The Role of Early Mathematical Models of Intelligence”, a consideration of how research findings were modeled and interpreted at the time by members of one side of the debate or the other. We then continue with the section “Further Developments, Debate, and Integration” which covers from 1950 to 1999, and is followed by a second section of “Mathematical Models Renewed” that explains how, in the early 1990s, mathematical advances helped integrate the two competing perspectives.

We conclude by covering the contemporary understanding of broad intelligences and, very briefly, their implications for education. Although increasing evidence exists for intelligences in the plural, most school curricula already are organized somewhat by subjects that correspond to those specialized mental abilities. And, although creative innovations have been recommended to address people’s individual strengths and weaknesses, relatively little well-controlled empirical evidence exists on the effectiveness of such programs. As some theoretical positions point out, intelligences can be thought of as a system of parts that operate together (Detterman, 1982).

One general intelligence or many intelligences? The origins of the debate: 1990–1949

Does human intelligence properly consist of one general intelligence to understand the world, or multiple, partially-distinct intelligences—that is, “intelligences” in the plural (Lubinski, 2004; Spearman, 1904; Thurstone, 1938). If there were one overall general intelligence, or *g*, then a single IQ could sum up a person’s intellectual prowess; if there were many, somewhat distinct mental abilities, then a more nuanced approach would be needed.

Spearman’s *g*

Working at the start of the 20th century, Charles Spearman initiated the debate over one-versus-many intelligences—pointing to evidence for the unitary quality of mental abilities. Spearman’s studies were inspired by the work of Sir Francis Galton. Galton had persuaded nine-thousand visitors to the 1884 International Health Exhibition at the South Kensington Museum in London, to pay 3 pence each to take a battery of measurements he believed might indicate intelligence—from head size and reaction time, to sensory acuity (color sense, good eyesight; Fancher, 1987, pp. 41–42).

Spearman took a somewhat different starting point. Visiting local schools, he indexed students by their class rank in such subjects as classics, language, and math; he also administered music and other sensory tasks. He next computed correlation coefficients among the students’ various class ranks and noticed that all the correlations were positive—a phenomenon that later became a signature feature of the relations among mental abilities, termed the *positive manifold*; there also were positive correlations with the sensory measures he administered. These correlations indicated that an individual’s mental abilities rose and fell together. That is, if a child were high on one mental ability, they tended to be high on all the others.

Spearman (1904) further suggested that any matrix of correlated test scores could be divided into two parts “the one great common Intellective Function” —the pure, general, rise and fall of ability across tasks, which he termed *g*—and the specific variability due to individual tasks (Lovie and Lovie, 1993, p. 310). In essence, Spearman developed a model in which he argued for the existence of two “levels”—a general intelligence at the peak to account for the common scores being high for some students and low for others, and, beneath that general capacity, the specific skills assessed by each of the individual tasks themselves.

Objections to the idea of a general intelligence were raised almost immediately, however, and the idea of one single “engine” behind problem solving (Spearman likened intelligence to a steam engine) seemed potentially objectionable.

Binet’s contribution

Across the English Channel in Paris, Spearman’s contemporary, Alfred Binet, set to work on how to improve the measurement of intelligence of school children (Binet and Simon, 1915). Public education in France had expanded greatly in the 1800s (Anderson, 1982); that expansion introduced questions such as which students could reasonably be educated in public schools and which students, owing to intellectual disabilities, might require special education. Working at the behest of an educational commission established by the French government, Binet constructed the first valid measures of school aptitude. His new tests, developed with Theophile Simon and Victor Henri, focused on children’s capacity to conceptualize, to reason, to compare objects, and similar tasks expected of them at school (Binet and Simon, 1915). Binet’s team refocused intelligence measurement away from features that Sir Francis Galton examined, such as head size and reaction time, to what students actually did in school. The teams’ measures included memory for concepts, verbal knowledge of objects, repetition of (i.e., memory for) numbers, placing objects in order of their weight, comparison of weights, and the ability to define abstract terms.

Although Binet conceptualized intelligence as focused on higher-level abstract reasoning, he believed that it might be both multifaceted and malleable (Beaujean and Benson, 2019, p. 201; Haney, 1984, p. 602). But Binet had a job to do: to develop a measure simple enough to be used by non-psychologists in school settings. And so he and his colleagues designed his tests—despite their varied subscales—to produce one easy-to-use overall score. The variety of scales employed on the test, however, inspired other researchers to look more closely at whether the diverse tasks might plausibly indicate more than one ability (Boake, 2002).

Thurstone's primary mental abilities and the advent of factor analysis

L.L. Thurstone, then at the University of Chicago, expanded on the tasks laid out by Binet, Henri, and Simon. Thurstone developed a group of diverse intelligence tasks, administering them to large samples of test-takers. To analyze his data, Thurstone introduced new approaches to *factor analysis*, a family of mathematical modeling techniques that could be used for evaluating correlation matrices. Factor analysis was to prove foundational not only to understanding the relations among intelligences, but to measurement in psychology more generally. We will turn to factor analysis shortly.

Whereas Spearman interpreted his matrices of correlations to reflect one general intelligence factor and many specific task factors, Thurstone proposed a set of seven independent intelligences he referred to as “primary mental abilities,” which included Reasoning, Perceptual Speed, and Word Fluency, among others listed in Table 1 (left-side column). Thurstone found evidence in support of his proposed primary mental abilities from a sample of college students who were relatively comparable in their IQ scores but who nonetheless differed in their respective scores on the primary mental abilities (Thurstone, 1938). Today, multiple, related mental abilities such as Thurstone examined are referred to as “broad intelligences.”

One more intelligence ... Thorndike's social intelligence

Beyond the central figures of the one-versus-multiple intelligence debate, other thinkers proposed additional candidates for intelligences. In 1920, Edward L. Thorndike proposed that there existed an intelligence for understanding people that he called *social intelligence* that involved “the ability to understand and manage men and women, boys and girls, and to act wisely in human

Table 1 Proposed broad intelligences.

Generic classes of broad intelligences	Thurstone's (1938) primary mental abilities	Gardner's (1983) multiple intelligences ^a	Regularly-studied intelligences ^b from Carroll's model (1993)	Potential additions and/or pending (various)
Abilities commonly regarded as more fluid				
Fluid intelligence	—	—	Fluid intelligence	—
General reasoning	Reasoning	—	—	—
Speededness	Perceptual speed	—	Processing speed	—
Working memory	—	—	Short-term memory	—
Abilities commonly regarded as more crystallized				
Verbal comprehension	Word fluency	Linguistic-verbal	Comprehension knowledge	—
	Verbal comprehension		Reading and writing	
Visuo-spatial	Spatial visualization	Visual-spatial	Visuo-spatial processing	—
Mathematical-quantitative	Number facility	Logical-mathematical	Quantitative reasoning	—
Long-term memory retrieval	Associative memory		Long-term retrieval	—
Other sensory	—	Bodily-kinesthetic	—	Tactile-kinesthetic ^c
		Musical	Auditory intelligence	—
Creativity			Creative intelligence ^d	
Practical	—	—	—	Practical
People-centered ^d	—	Intrapersonal	Emotional intelligence	Personal intelligence ^e
	—	Interpersonal	—	Social intelligence ^f

^aAlthough most the other classifications are based on psychometric tests, Gardner's group were determined by his logical argument that each intelligence met eight criteria, such as having plausible bases in human evolution, an associated brain structure (isolation by brain damage), savants in the area, and also including psychometric criteria.

^bThe most regularly studied broad intelligences were compiled more recently (Bryan and Mayer, 2020). Although not a part of the original review because few studies employed it, creative intelligence also is included owing to its theoretical place in the original CHC and other models. Emotional intelligence was confirmed as a member more recently (MacCann et al., 2014).

^cBodily-kinesthetic (Roberts et al., 1997).

^dPeople-centered is a class suggested by Mayer to encompass emotional, personal, and social intelligences.

^ePersonal intelligence (an intelligence about personality) (Mayer et al., 2012, 2019).

^fSocial intelligence (e.g., Thorndike, 1920; Weis and Süß, 2007).

^gIncluded under retrieval fluency in Carroll (1993).

relations" (Thorndike, 1920; Thorndike and Stein, 1937). Several attempts at measuring this intelligence were made, but with equivocal success—the ability appeared to blend imperceptibly into general intelligence (Hunt, 1928; Thorndike and Stein, 1937; Walker and Foley, 1973). Surprisingly, a good measure of social understanding has yet to be developed although progress continues (Weis and Süß, 2007; Conzelmann et al., 2013), and it therefore appears in the "Proposed/Pending" column to the right in Table 1.

More extremely opposed than warranted?

With the advantage of hindsight, we observe that both Spearman and Thurstone made unintentional errors in their work that exaggerated their differences. Spearman, for example, had derived a (correct) formula to adjust correlations upward so as to compensate for errors in measurement—now known as the *correction for attenuation*. The formula was a useful one, however, Spearman appeared to have misapplied it initially, leading him to believe that the many positive correlations he witnessed would be near $r = 1.0$ once error was corrected. This position was widely criticized at the time and in fact overstated the case (Fancher, 1987, pp. 90–92). Thurstone, on the other hand, used samples of students who were so similar in their ability as to reduce the magnitude of the correlations he observed—a phenomenon now known as restriction of range. This led him to believe that the correlations among mental abilities were lower than they actually were. He swiftly corrected his viewpoint once the error became clearer to him (Haier, 2016, p. 34; Thurstone and Thurstone, 1941). By the 1940s, the correlations among mental abilities were generally understood to be moderate—residing in a gray area between the one and many—and making the resolution of the issue challenging.

The role of early mathematical models of intelligence

Basic models

In the debate over single versus multiple intelligence in the early 20th century, psychologists generally argued on the basis of (a) mental test data that they or others had collected and (b) applied mathematical models from a family of techniques called "factor analysis" to the data. To understand the debate over one versus many intelligences, therefore, it helps to have some introductory knowledge of how factor analysis operates, and we therefore pause our historical review of the debate here to describe some of the basic techniques used through the 1950s.

Factor analysis is a method developed to examine and interpret the many correlations among intelligence tasks at once (and its use has broadened to many other areas of psychology since). The technique groups together variables that are (relatively) highly correlated with one another and separates other variables that are less related. The key protagonists in this debate generally assembled a group of mental ability tests, administered it to a sample of research participants, and then analyzed the data.

As a first step in such a data analysis, a researcher will calculate a matrix of correlations among people's scores on the mental ability tasks. Here, we present a correlation matrix employing just four mental tasks so as to keep our example simple, but more such tasks are desirable when conducting actual research. The starting matrix is shown toward the top of Fig. 2 in the "Step 1" column, where the correlations among the tasks range between $r = 0.35$ and 0.48 . (The Fig. 1 data provide a reasonable facsimile of actual findings). Factor analysis is then employed to evaluate the matrix and to sort test scores into groups called *factors*.

Understanding a factor model of g

Because the four mental tasks represented in the first correlation matrix in Fig. 1 (under the "One-Factor Case") exhibit moderate, positive correlations with one another, their relations suggest there is just one general intelligence—just as Spearman had speculated. We have applied factor analysis to the correlation matrix to carry out the second step. This step uses matrix algebra to reorganize the correlations in a different form, indicating which tasks might cluster together, and which are distinct. The results of the analysis show a single general factor, indicated under the Roman numeral I (Fig. 1, Step 2 column). Each number beneath the Roman numeral represents the correlation between the original test scores of T1 through T4 with the obtained factor for that particular sample of people. This same result can be represented pictorially and is indicated in the final panel to the right. There, the observed four tasks are represented as squares (directly measured scores) and the general factor is represented as an oval (a latent, i.e., inferred, variable). The lines connecting them and the numbers beside them represent the four loadings (i.e., correlations) between the task and the factor.

Primary mental abilities (intelligences in the plural)

The next row down of Fig. 1 proceeds through the same steps. This time, however, the starting correlation matrix shows that Tasks 1 and 2 are correlated $r = 0.48$, and Tasks 3 and 4 are correlated $r = 0.45$, but Tasks 1 and 2 are relatively uncorrelated with Tasks 3 and 4. If Thurstone saw this, he would say there were two factors: The first representing Tasks 1 and 2, and the second representing Tasks 3 and 4. And, indeed, the factor analysis yields two independent factors (Fig. 1, middle). Tasks 1 and 2 correlate with (load on) Factor I, $r = 0.69$ and 0.69 , but not appreciably on Factor II. Tasks 3 and 4 correlate with (load on) Factor II, $r = 0.67$ and 0.67 , but not on Factor I. A simple pictorial version of the model is indicated to the right. These simplifications omit some information, including the possible correlations between Factors I and II as well as error terms that indicate degrees of measurement precision.

Fig. 1 From correlation matrices to factor models The variables T1 through T4 of this example represent four mental tasks administered to 1000 participants. Each row begins with a different (hypothetical) correlation matrix that illustrates a given relationship among the mental tasks: A one-factor, two-factor, and two-factor hierarchical case are indicated beneath each of the row headings in the first column. Each of the correlation matrices were subjected to a factor analysis. In the Step 2, “Factor Extraction” column (middle column), the roman numerals designate the first and second factors extracted for the one- and two-factor cases. The numbers beneath the roman numerals represent the estimated correlations between the four individual tasks and the two factor(s); those correlations are referred to as factor loadings. The final “Diagrammatic” column to the right represents a pictorial depiction of the results. Several further details for those interested are that the one- and two-factor solutions were both exploratory factor analyses employing principal factor extractions, the two-factor version employed an oblimin rotation, and the hierarchical model was a confirmatory factor analysis. All analyses were carried out in R. The figure is reproduced from an online version that is accompanied by further details of the analyses (Mayer and Bryan, 2021).

To carry out such analyses in the first part of the 20th century often required extensive investment of time and resources; in the better-funded laboratories, graduate students employed mechanical calculators to obtain the correlations they and their professors needed, and then the research team carried out transformations of the matrices to come up with a particular solution; sometimes a mechanical geometric apparatus was constructed to further transform the correlation matrices.

Hierarchical (second order) models

Perhaps the above tedious work discouraged most laboratories from considering anything more complex. There were, however, more adventurous souls who suggested that one could “stack” factors in a hierarchy. [Thurstone \(1944\)](#) developed an idea of “second order factors”, which [Schmid and Leiman \(1957\)](#) further refined and relabeled a *hierarchical* model—the name that stuck. Hierarchical models permitted intelligence researchers to obtain a general factor that corresponded to general intelligence

(Spearman's g), and then to subdivide it into a second set of factors that represented broad intelligences. These broad intelligences were defined at a lower level by the specific indicators (mental ability tasks), T1 to T4 in this example, of each broad intelligence. This hierarchical situation is depicted in Fig. 1, bottom row.

In the starting matrix, Tasks 1 and 2 still correlate highly with one another, and Tasks 3 and 4 also correlate with each other; notice, however, that now we have introduced moderate positive correlations among the tasks throughout the matrix. Factor analyzing that matrix yields evidence for both an overall g and two broad intelligences. The model is specified in some detail in advance, which includes setting loadings to zero where none are expected. The factor solution now shows the loadings for Factors I and II (as before), and also the loadings of the two factors on a more general factor. The diagram representing the result in the far-right panel indicates that there exists a general intelligence factor (g), under which is subsumed two broad factors (I and II). The problem remained, however, that some researchers obtained robust one-factor solutions, others, multiple factors, and rather few researchers tried the more demanding second-order, hierarchical solutions.

Further developments, debate, and integration: 1950–1999

Cattell and Horn's Gf-Gc model: multiple manifestations of g

Raymond B. Cattell, a student of Spearman, was well-versed in applying factor analysis to data of personality generally, and mental abilities specifically. Cattell speculated that, subtly embedded in many correlational patterns among intelligence tasks might be evidence that g divided into two subsidiary, highly correlated factors that were, "so highly cooperative, i.e., so similar in most loadings" that earlier factor analytic methods had missed them (Cattell, 1961, p. 742).

One of the two factors, Cattell argued, loaded on tasks like inductive reasoning and numerical ability, and appeared to represent a flexibility or fluidness in people's reasoning, independent of a person's education or culture; Cattell labeled this *fluid general ability* (Gf). The other factor, which loaded on tasks pertaining to verbal ability and stored knowledge acquired through education and culture, Cattell labeled as *crystallized general ability* (Gc). John Horn, a student of Cattell, expanded Gf-Gc theory to include additional aspects of general reasoning that emerged from intelligence tests, such as general fluency, which pertained to recall and recognition, general speediness (Gs), which involved the ability to rapidly perceive relations or solve problems, and general visualization (Gv) which involved mentally manipulating and transforming the spatial patterns among objects (Cattell and Horn, 1978; Horn and Cattell, 1966). Cattell and Horn's view was influential in the field and would be raised again in the 1990s.

Howard Gardner's multiple intelligences

The debate over multiple intelligences was a matter chiefly carried out by intelligence researchers studying intelligence tasks and using factor analysis. But in the early 1980s, Howard Gardner introduced a novel theoretical view of intelligence with his book entitled "Frames of Mind" (Gardner, 1983), in which he employed eight criteria to determine what was (and was not) an intelligence. Among the criteria were that symbolization was involved, that evolutionary pressures would require the intelligence for survival, and that brain areas could be isolated for the mental ability as a consequence of brain damage, or in cases of savants. Although intelligence testing was on Gardner's list as well, it appeared last (and in Gardner's view, perhaps, least).

To argue for the existence of linguistic-verbal intelligence, for example, Gardner described poetry (and language more generally) as operating with symbols; he detailed the often challenging, trial-and-error process that the choice of the right word can require; and he wrote of the need to understand semantics, syntax, phonology, and the core operations of language in communication. Gardner profiled the work that poets sometimes engaged in to compose their writings, drawing in part on the correspondence and notes of T. S. Eliot (Gardner, 1983, p. 77). He used examples of hyperlexic children, who learn to read at two or three years of age, and the localization of syntax understanding in part to Broca's area of the brain. Collectively, these and other topics allowed him to build a case for the intelligence in an argument that is largely independent of psychometric findings.

The remainder of Gardner's intelligences included visuo-spatial, logical mathematical, bodily-kinesthetic, musical, and intra- and interpersonal (see Table 1). Although he used substantially different criteria from those of other psychologists, Gardner arrived at a list much the same as others had proposed (other than, perhaps, his bodily-kinesthetic). More recently, some researchers have continued to localize brain functions relevant to Gardner's (and other intelligence researchers') lists (e.g., Shearer, 2020).

Yet Gardner made two arguments that were viewed as untenable to those who regularly worked in the area. First, although Gardner acknowledged that a general intelligence might exist, he regarded his multiple intelligences as "not subsumed under g "—implying that what he had identified was not a part of (or necessarily correlated with) the rest of human intelligence (Gardner, 1999, p. 87)—a claim that flew in the face of a large and consistent database of findings (both then and now) that showed otherwise. Second, Gardner contended that "having a battery of ... tests is not consistent with the major tenets of the theory," thereby actively discouraging any empirical tests of his approach. Although Gardner had his reasons for staking this anti-testing position (concerns over the potential misuse of his theory; Gardner, 1999, pp. 80–81), it rendered his proposals unverifiable by any methods of the day. But science requires collecting data relevant to theoretical positions and interpreting that data (e.g., Strevens, 2020), so we return to such work next, examining the continued progress of research into general intelligence and its constituent intelligences.

Mathematical models renewed

Comparative model fitting

With factor models fairly-well envisioned, and the major models of intelligence relevant to 20th-century research in place, a further issue remained: The initial techniques of factor analysis could not settle the one-versus-many debate. Different intelligence tests often correlated at a moderate level of about $r = 0.25\text{--}0.45$. Such correlational levels were neither perfectly correlated nor entirely independent of one another.

Given the mathematical techniques of the day, researchers of the 1950s and 1960s often were forced into one of two positions—which they could find evidence for depending on the kind of factor analysis they used and the nature of their data set. The first position was that mental ability tests reflected a pure general intelligence accompanied by a kind of residual sludge of error due to specific tasks. The second position was that each distinct class of intelligence tasks represented a truly independent intelligence, and that these intelligences appeared to correlate among themselves somewhat, perhaps due to some common artifact such as the test-taker's understanding of written or spoken instructions. [Gardner \(1993, p. 17\)](#) commented, "... given the same set of data ... using one set of factor-analytic procedures ... supports the idea of a 'g' factor; using another ... it is possible to support ... relatively discrete mental abilities," and no resolution was in sight. But change would arrive faster than Gardner had anticipated.

An effort had emerged across several disciplines beginning in the 1910s to build mathematical models that could describe the relations among multiple, correlated variables; these early models, which included path analysis, evolved into a broader set of techniques that ultimately would be integrated with the work of factor analysts ([Matsueda, 2012](#)). Those who developed the techniques hoped not only to model complex relations but also to develop statistical tests for *how well* a given model fit the data. In the late 1960s, several psychometricians solved the basic problem of assessing the fit of a given factor model ([Jennrich and Robinson, 1969](#); [Joreskog, 1969](#)). Their approach, under the label Structural Equation Modeling (SEM), provided powerful new methods for modeling data ([Boomsma, 2000](#); [Matsueda, 2012](#)). Factor analysts now could compare factor models to select the models that fit data the best, and discard the rest. Although these innovations predated Gardner's work by 10-plus years, the complexity of the techniques, their unfamiliarity, and the relative unfriendliness of the initial software for carrying out the analyses, meant that the use of SEM filtered slowly through the field at first. Nonetheless, intelligence researchers and researchers in many other fields began to employ the technique regularly, and as the software improved, ever-more sophisticated models could be tested on data.

John Carroll and a key outcome of comparative model fitting

In 1993, John Carroll published a review and reanalysis of 400 datasets from intelligence research throughout the 20th century using SEM. For a number of years, Carroll had visited intelligence laboratories at many universities and asked the researchers there for any data sets they might share that included correlations among specific intelligence tasks for large samples of test-takers (The first author was present at one such in-person visit to Douglas Detterman's laboratory at Case Western Reserve University around 1980). Carroll compiled the correlational tables he collected and subjected them to a series of factor models, testing the fit of the models using confirmatory factor analysis techniques from SEM. The result was a three-tiered model later termed the Cattell-Horn-Carroll (CHC), or three-stratum model, that arranged general intelligence at the top, eight broad intelligences (akin to Thurstone's primary abilities and including Cattell and Horn's Gf and Gc) at the second tier, and specific tasks below. Fairly quickly, researchers regarded the CHC model as having ended the debate over whether there were multiple intelligences, or just one, and tied it up in a rather elegant bow: Both positions were correct, and they could be integrated in a single hierarchical model. We illustrate one such version of the model in [Fig. 2](#), drawing on a recent meta-analysis of correlations among intelligence tests ([Bryan and Mayer, 2020](#)).

Reproduced from [Bryan and Mayer \(2021a\)](#).

What do we know of these multiple intelligences today?

With the growing awareness of Carroll's and others' contributions to model-fitting, the field changed markedly. By 2001, Ian Deary was able to conclude regarding the CHC model:

... there is consensus that there is a general cognitive factor that accounts for about 50% or so of the variance in a broad assembly of mental tests given to a large sample of the population ... there is still variance attributable to separable "group" factors of intelligence. Beyond the general factor and group factors some test performance variance ... is manifest in very specific mental abilities. This so-called three-stratum model affords freedom from otiose arguments about being "for or against the general factor."

Deary (2001, p. 127).

Intelligences—or *broad intelligences*, using today's terminology—are a now well-established part of understanding how people solve problems.

What are the recognized broad intelligences of today?

Bryan and Mayer (2020) reviewed 61 studies that contained intelligence test data from 20,498 participants. From those studies, they concluded that there had been 10 widely-studied broad intelligences from the decades surrounding Carroll's integrative model (see Fig. 2). These 10 included the now familiar instances of fluid intelligence, comprehension knowledge (i.e., verbal-comprehension), visuospatial processing, short-term memory retrieval, processing speed, quantitative reasoning, and more recently-proposed intelligences described next.

Still newer intelligences?

Carroll's integration of broad intelligences with *g* did not stop the search for further areas of intelligence. For example, Mayer and Salovey proposed an ability model of emotional intelligence (Mayer et al., 2016; Salovey and Mayer, 1990) and recent research provides evidence in favor of its status as a broad intelligence (MacCann et al., 2014). More provisionally, there may also exist a *personal* intelligence—an intelligence about personality—that appears partially distinct from emotional intelligence (Mayer, 2008; Mayer et al., 2019); and other researchers have picked up on Gardner's idea of a kinesthetic intelligence, finding some supportive evidence (Roberts et al., 1997).

Another group of intelligences suggested by Robert Sternberg included the analytical, creative, and practical (Sternberg, 1985; Wagner, 2011)—of which analytical and creative already appeared in the CHC model, but not the practical. The kinesthetic, personal, and practical intelligences appear in the "Potential Additions" right-most column of Table 1 toward the bottom (Mayer et al., 2012, 2019; Roberts et al., 1997).

Relations among broad intelligences

While the number of mental abilities considered at the second stratum of the CHC model paints a nuanced picture as to the breadth of human intelligence, some researchers have expressed concern over their large number. Hedlund and Sternberg (2000) asked whether there might be "Too many intelligences?" That surely would be the case if the broad intelligences correlated too highly among themselves. But a recent meta-analysis of the area determined that the average estimated correlations among the broad intelligences across two alternative factor models used in the literature were $r = 0.58$ and $r = 0.62$, or about $r = 0.60$ overall (Bryan and Mayer, 2020). This level allowed for distinctions among multiple, meaningfully different intelligences. The exact number of intelligences—awkwardly large though it sometimes may seem—appears to be more a neuropsychological consequence of human evolution than of researcher preference.

Organizing the broad intelligences

But with new intelligences proposed, is there some way to organize or simplify these broad intelligences? In the same meta-analysis discussed above, Bryan and Mayer (2020) refactored one of their composite correlation tables and re-encountered an older finding: the intelligences did indeed seem to divide according to their more-fluid versus crystallized qualities, as pointed out earlier by Cattell and Horn (Cattell, 1963). The fluid-intelligence factor loaded on fluid intelligence itself, with visuospatial processing, and processing speed; the crystallized abilities included long-term retrieval, reading and writing, and emotional intelligences.

Additional divisions have been proposed as well. Mayer suggested a possible continuum of content-focused broad intelligences from a group of "thing-centered" intelligences typified by visuo-spatial and quantitative reasoning abilities, to a group of "people-centered" intelligences, typified by emotional, personal, and social intelligences (Mayer, 2018). A second meta-analysis covering a set of 87 studies of thing- and people-centered intelligences indicated the empirical viability of a people-versus-thing continuum of reasoning as applied to the broad intelligences of the CHC model (Bryan and Mayer, 2021b).

Another proposed organization divided such intelligences into those related to perceptual processing (e.g., auditory, kinesthetic), those related to controlled attention (e.g., fluid reasoning and working memory), and those related to acquired knowledge (e.g., comprehension-verbal, quantitative) with an additional set of speed and fluency abilities (e.g., processing speed and speed of memory retrieval). This elaboration on the original fluid versus crystallized distinction also may prove viable (Schneider et al., 2016).

Implications for educators and for education

Research to-date suggests that education has a healthy effect on students' intellects: that each year of schooling a student undergoes will raise their IQ from 1 to 5 IQ points overall (Brinch and Galloway, 2012; Ritchie and Tucker-Drob, 2018). Like a rising tide, such education may float all boats together, for the most part (Gustafsson and Undheim, 1992; Undheim, 1976). This general improvement may be a consequence of the requirement by most educational systems that younger students' studies are distributed across academic subjects. The general increase in children's mental ability acknowledged, adult intellectual development may be different, as education and intellectually-demanding work often require further specialization in one or two broad intelligences relative to the rest (Ackerman, 2000).

Given the correlations among broad intelligences, the possible differences in ability level across intelligences are such that most students likely will benefit from many forms of educational approaches. The attempt to match a student to a particular form of instruction based on their constellation of broad intelligences may be unneeded, although exceptions exist where ability in a particular area is impaired, for example, by a specific learning disability.

That said, two recent meta-analyses indicated that the applied use of multiple intelligence theory in the classroom may enhance classroom achievement (Aydin, 2019; Bas, 2016). Both meta-analyses were motivated by the implementation of a Turkish Ministry of Education primary school program that promoted sensitivity to "multiple intelligences and the individual differences of students" (Aydin, 2019, p. 2). The appendices to the Ministry's program included two examples of the kinds of lessons that might be carried out. We will describe the Bas work as representative of the two.

Bas (2016) examined 75 studies of the Turkish program's outcomes and found substantial positive effective sizes for student achievement, comparing such multiple-intelligence focused classrooms to control classrooms. Although carefully completed, Bas' work left open whether such improvements might be due to research artifacts included under the broad umbrella of *Hawthorne Effects* (Adair, 1984; Chiesa and Hobbs, 2008), which can include student improvements due to better-thought-out lesson plans, communicating to students that one is using special teaching techniques, or simply disrupting routine in a positive way. As Bas puts it (2016, p. 1836) "even the planning stages of these [multiple intelligence] activities are full of fun, colorful, and creative works" (p. 1836).

In such applied work, tracking how a curriculum is implemented across different settings, and whether assessments of multiple intelligences in students actually were carried out validly, as well as the methods used to match students to their given intellectual strength(s) is challenging. All this is not to deny the creative contributions made by advocates of such approaches (see, for example, Kornhaber et al., 1990; Kornhaber and Gardner, 2006). Further, fun activities that promote student learning are surely worth cheering on. But the research does still leave open the question of the exact causes of educational improvements in the area.

Conclusions and reflections

Consistencies across the past years

The drama and the debate of the early 20th century over whether intelligence is singular or plural has given way to researchers' development of better statistical and measurement techniques to study intelligence. Collectively, the evidence indicates that multiple, broad intelligences do exist, partially independent of general intelligence. The list of those broad intelligences has been remarkably stable over the past 40 or so years, with the exception that emotional intelligence has been added to the group (Mayer et al., 2016), and personal and social intelligences may be further reasonable candidates (Bryan and Mayer, 2021b; Mayer et al., 2019).

With progress over the years gratefully acknowledged, it remains of interest that if one compares Thurstone's Primary Mental Abilities from 1939 to those of Gardner in the 1980s, who recall, employed entirely different criteria to identify intelligences, the continuity is fairly striking. The Cattell-Horn-Carroll (CHC) model, in turn, updates and integrates both conceptions. New approaches seek to organize the broad intelligences themselves into conceptual groups, although this undertaking is just beginning (Bryan and Mayer, 2021b; Mayer, 2018; Schneider and Newman, 2015).

Considerations regarding education

It seems likely that students find some classroom topics more appealing than others owing to their ability and interest in a given subject. Science, math, and art all potentially draw on spatial reasoning, composition on verbal skills, and literature, perhaps, on verbal skills and emotional and personal intelligences. By surrounding students with subjects, some of which they may excel at, we are naturally enhancing thinking in these areas. That makes sense because the broad intelligences—as Gardner himself pointed

out—have bases in our evolutionary past, and for the most part they remain relevant to mental development today, as people grapple with diverse kinds of problem solving in their everyday lives.

Societies are becoming more information dependent rather than less, and the ability to think well and clearly is more important for citizens than ever before. For that reason, education—and the increases in intelligence it brings about—are crucial contributions to people's broad and general intelligences—and to our future.

Introduction

Knowledge is a fundamental concept in education. Indeed, we typically think of learning as the acquisition of knowledge. This knowledge is then used to solve new problems and to support future learning. Knowledge begets knowledge. Hence, understanding what knowledge is, how it can be measured, and how it can be used in future learning is a critical foundation for educators. In this article, we first define knowledge in the context of information processing and mental model building with emphasis on knowledge as an asset. We then describe the multifaceted nature of knowledge and how different types and dimensions of knowledge can be assessed and how these qualities of knowledge relate to learning. Finally, we explore how an asset-based approach to knowledge building can enhance learning and provide recommendations for how educators can help students to leverage what they already know to build their knowledge base.

Defining knowledge

We intuitively think of our knowledge as all of the information that we have learned in the past, our past experiences, our skills (e.g., reading, writing, math, riding a bike). It is the stuff that is in *there*, and the stuff that we try to find when we need to complete a task, answer a question, or simply think about an event. In the field of education, knowledge is the objective: educators strive to increase students' knowledge of various topics (e.g., history, science) and their ability to complete various tasks (e.g., solve math problems, write an essay, read a complex science text). The objective is to enhance students' ability to demonstrate their knowledge and use and apply their knowledge flexibly across multiple situations.

The study of knowledge has a rich history across a variety of fields. Indeed, there are few fields of study that do not contemplate the nature of knowledge.¹ For our purposes, we define knowledge as "all of the information stored in one's memory" (McCarthy and McNamara, 2021; see also Greene et al., 2016a). This information may be correct or incorrect, coherent or incoherent, and the information may be more or less accessible in a given situation. Knowledge is not the process or success of accessing information, but rather it is all of the information that is potentially available from long-term memory.

In educational research and practice, a central objective is to increase learners' knowledge and to make that knowledge more accurate and more coherent. Newly learned knowledge becomes prior knowledge, which can then be leveraged in future situations to create new knowledge. Thus, in addition to measuring what a student has learned in a given task or unit, researchers and instructors are also interested in what a learner already knows before the activity begins, or their *prior knowledge*. Prior knowledge is a strong predictor of comprehension and learning (Dochy et al., 1999). Prior knowledge plays a role in a variety of processes involved in learning. Prior knowledge affects *how* people remember textual information (Bartlett, 1932) and how much information they recall (Bransford and Johnson, 1972; Langer and Nicolich, 1981). Prior knowledge affects how readers make use of comprehension strategies (Cromley and Azevedo, 2007; McNamara, 2004). Prior knowledge also allows learners to more effectively process information and recall it more quickly (Graesser and Clark, 1985; Trabasso and van den Broek, 1985). Those with more knowledge are also better able to identify critical information (Afflerbach, 1990; Chi et al., 1981) and ignore irrelevant information (McNamara and McDaniel, 2004; Voss et al., 1980). Thus, knowledge is not only an outcome, but also a critical predictor of future learning.

¹For a comprehensive review of the philosophical and educational history of the study of knowledge, we recommend Murphy et al. (2012).

Considerations of knowledge are crucial to understanding student outcomes across the spectrum of disciplines and contexts (e.g., Goldman et al., 2016; Kendeou et al., 2011).

Knowledge: deficit vs. asset

When we consider knowledge, it is important to consider whether we conceptualize it as a glass half empty or a glass half full. A deficit (half empty) model of knowledge dominates education and educational research. One considers what a student lacks in knowledge in order to fill those gaps—*because* the objective is to remedy knowledge gaps or deficits by *giving* the students the knowledge that they lack. Alternatively, an asset model of knowledge attempts to discern the knowledge that a student has in order to capitalize and build upon it.

No one comes into the picture completely lacking knowledge. A student who knows very little about science, still knows some things about the world, people, events, and relations. In a deficit framing, the goal of instruction would be to *give* student knowledge about science. By contrast, an asset-based approach aims to capitalize on the student's knowledge about the world in order to build knowledge about science (Scardamalia and Bereiter, 2005). The notion that we can give a student knowledge is a misconception about learning that has been reinforced by assumptions that *giving* lectures or having students read a textbook are (by themselves) sufficient for learning (McNamara, 2010). Unfortunately, that is not the case—students cannot merely consume knowledge. Knowledge is an asset to be built upon, capitalized, used, and enhanced.

Asset-based approaches also emphasize the need to recognize culturally-bound knowledge. Work in culturally-responsive pedagogy highlights that minoritized students do not often see themselves or their lived experiences presented in the classroom and in the curriculum. This can suggest to students that the knowledge that they have is not important or relevant to the classroom context and can artificially suggest to instructors that these students *lack* knowledge and overlooking the *cultural funds of knowledge* that they do possess (Gay, 2018; Ladson-Billings, 2009; Moll et al., 1992). Culturally-responsive pedagogies argue for the recognition and leveraging of the knowledge that students have, rather than focusing on what they do not have. For example, the *Cultural Modeling Framework* (Lee et al., 2004; Lee, 2007) capitalizes on students' informal knowledge and helps them to translate this knowledge to formal coursework (Risko and Walker-Dalhouse, 2007).

Conceptualizing knowledge as an asset rather than a deficit has the potential to radically change education. Considering knowledge as an asset means that educators must consider multiple aspects of knowledge rather than just the amount of knowledge specifically related to a target domain. It means that educators must consider how to build upon knowledge, rather than simply add information. Here, we discuss how to measure knowledge from multiple angles as well as methods to prompt students to use the knowledge that they have in order to construct new knowledge.

Measuring knowledge

Measuring or assessing what a student knows involves not only what concepts are known, but also how those concepts are connected and organized in memory. In addition to understanding *what* information or *how much* information is available in long-term memory, researchers who study knowledge and learning are most interested in how information is organized or structured. How researchers measure knowledge reflects assumptions about how information is stored and represented in memory. Cognitive theories of comprehension and learning (e.g., Anderson and Lebiere, 1998; Johnson-Laird, 1989; Kintsch, 1988) suggest that knowledge can be represented in a connectionist network as a series of nodes (concepts) and links (relations). This network is conceptualized as a multi-layered, multi-dimensional *mental model* or *mental representation*. If a student were to read the sentence "The dog was asleep on the couch," information such as "cat" and "living room" are likely to also be activated in memory through *spreading activation* because these terms are strongly connected to the nodes of "dog" and "couch," respectively. The more and more connected information is, the easier it is for learners to activate and integrate that knowledge in future learning. Mental models that have more densely connected nodes are said to be more *elaborated* and more *coherent*. Thus, in order to measure knowledge, researchers explore the quality of the learner's mental model. Of course, these mental models are not directly observable. Researchers use a variety of tasks and measures to make inferences about the nature of the learner's mental model.

Learning assessments are used to evaluate what a student has learned over time (e.g., a post-reading quiz and end-of-semester final exam). These assessments often use a variety of types of questions to assess different features of the learner's mental model. Surface level questions (e.g., recall, definitions) are designed to evaluate what information is remembered to assess which nodes are present and available. Other tasks, such as inference verification, transfer, or application questions require the learner to integrate information. Thus, they are designed to target the coherence of the learner's mental model. While researchers often carefully develop post-activity knowledge assessment, prior knowledge tests often consist of self-report items, vocabulary recognition, or multiple-choice tests to gauge general familiarity with the topic at hand. While these types of tests are easy to develop and administer, they are often less rigorous and are often not clearly aligned to measuring the various qualities of the learner's existing mental model (Dochy et al., 1999; McCarthy and McNamara, 2021).

In order to evaluate the quality of a mental model, researchers must be sensitive to the fact that knowledge is multi-faceted and multi-dimensional. We borrow from de Jong and Ferguson-Hessler (1996) who argue that knowledge is comprised of different *types* of knowledge and that there are multiple *qualities* or *dimensions* of each of these types of knowledge. These different aspects of knowledge contribute to learning in different ways. Thus, a richer understanding of the nature of knowledge can help educators to consider

which types or dimensions of knowledge are most critically relevant to a given learning task—again, not necessarily what is missing, but perhaps more importantly, what the learner and the learning environment brings to the table.

Types of knowledge

Researchers have identified and distinguished between various *types* of knowledge (e.g., Alexander et al., 1994b; Anderson, 1989; de Jong and Ferguson-Hessler, 1996; Dochy and Alexander, 1995; Kendeou and O'Brien, 2015; Tulving, 1972). Rather than drawing from a specific typology or taxonomy or providing an exhaustive list of the variety of terms and definitions, we describe the most commonly referenced types of knowledge. The boundaries between these types of knowledge can often be relatively fuzzy and the different types of knowledge are also not mutually exclusive.

One common distinction is whether the knowledge is explicit or implicit. **Explicit** knowledge is information that is in conscious awareness, whereas **implicit** or *tacit*, knowledge is assumed to be acquired and used without conscious awareness (Jacoby and Witherspoon, 1982). For example, a person might learn the words to a popular song without intentionally studying the lyrics or may not be able to consciously articulate the steps they take to stay upright on a bike. While explicit knowledge is easy to probe for, implicit knowledge is relatively challenging to assess because the learner may not recognize that they have the knowledge or they may be unable to clearly articulate or express that knowledge.

Perhaps the most familiar type of knowledge is declarative knowledge (Squire, 1992). **Declarative**, also sometimes called conceptual knowledge, refers to predominantly explicit knowledge about facts and concepts (*semantic* memory) as well as knowledge of personal and world events (*episodic* memory; Tulving, 1972). In the context of learning in formal settings, declarative knowledge is often considered the “content knowledge” that one possesses relevant to the current task. Declarative knowledge is “knowing what” or “knowing that.” By contrast, **procedural** knowledge refers to “knowing how” (Ryle, 1949). Procedural knowledge refers to knowing the sequence of steps needed to complete a task (e.g., riding a bike; long division). Often procedural knowledge is either gained implicitly or is taught explicitly and becomes more implicit, or *proceduralized*, over time. Procedural knowledge has largely been studied in the context of problem solving and mathematics (e.g., Anderson and Fincham, 1994; McNamara, 1995; Rittle-Johnson and Siegler, 1998). Relatedly, **embodied** knowledge is intrinsically tied to bodily perceptions and actions. Embodiment of concepts by linking them to perceptual and motoric movements can be used to facilitate meaning making and learning (Glenberg, 2011; Glenberg et al., 2007).

Metacognitive knowledge refers to the “awareness and knowledge about one’s own cognition” (Pintrich, 2002, p. 219; see also Flavell, 1979). Metacognitive knowledge is the information about one’s own knowledge, such as whether you know more or less about one topic compared to another or how much you know as compared to the average person or a peer. Metacognitive knowledge also refers to knowledge of particular learning strategies and the conditions under which one would deploy the strategy or strategies. Knowledge of what one knows, or perhaps more importantly, what one does not know, can help guide learning. Thus, metacognitive knowledge and metacognitive monitoring play critical roles in theories of self-regulated learning (Griffin et al., 2013; Thiede et al., 2003; Winne, 1996, 2018).

Epistemological knowledge refers to the knowledge of “ways of knowing.” Measures of epistemological knowledge (see also epistemic cognition, epistemic thinking, epistemological beliefs, epistemic frames) evaluate the degree to which a person views knowledge as certain or uncertain, simple or complex, whether knowledge or truth is derived internally by the individual or externally through authority (e.g., Greene et al., 2008, 2016b; Hofer and Pintrich, 1997; Schommer, 1990; Wood and Kardash, 2002). A student’s epistemological beliefs can vary across topics and disciplines (Bråten et al., 2009; Buehl et al., 2002). Further epistemic knowledge is predictive of performance across a variety of domains (see Greene et al., 2018).

In some traditions, *beliefs* are considered to be a type of knowledge. A belief is generally defined as an individual’s acceptance that a statement or information is true or represents something that exists. As such, researchers and educators often view knowledge and beliefs as separate constructs; beliefs reflect a greater level of subjectivity and affect, whereas knowledge is often assumed to be more objective in nature (see Murphy and Mason, 2006). Research suggests that learners’ beliefs (including their general and topic-specific epistemologies and attitudes) influence the ways in which knowledge is accessed and applied (e.g., Bråten et al., 2011; List and Alexander, 2017; Schiefele, 1990). Thus, beliefs are undoubtedly an important part of the learning process, but reflect, at least to some extent, a distinct construct to consider *in addition* to knowledge.

In the context of education, another critical type of knowledge is **disciplinary** knowledge, or knowledge related to learning in a particular field, discipline, or domain. Disciplinary knowledge intersects with other types of knowledge in the sense that learners can possess knowledge within the discipline (e.g., declarative facts about a topic, procedural steps to complete a process), but also knowledge about the discipline or domain itself (e.g., epistemic frames, learning goals). For example, literary experts are not only more familiar with common literary themes and conventions, but they also have the knowledge that literary reading encourages nonliteral interpretation and exploration of how the language of the text works to invite that interpretation (McCarthy, 2015; McCarthy and Goldman, 2019). Learning can be particularly challenging when students’ domain-specific epistemological beliefs are mis-matched with the underlying assumptions in domains. For example, students may think of science as inarguable facts. Science experts, on the other hand, recognize that science is subject to multiple interpretations and theories as well as revisions based on new empirical findings (Bråten et al., 2011; Elby et al., 2016; Goldman et al., 2016; Lederman, 2007). Students whose knowledge does not align with this conception of the nature of science may have difficulty synthesizing across conflicting findings or reasoning between competing hypotheses.

Another important, but commonly overlooked distinction is the context in which the knowledge is gained. Knowledge can be acquired in **formal** learning environments (i.e., “school knowledge”). However, learners also acquire sophisticated knowledge from **informal** learning in everyday activities (Saxe, 1988; Scribner and Cole, 1973). Thus, this distinction is not a feature of the information itself, but rather meta-information about the source of the knowledge. Informal knowledge is often more implicit in nature. Researchers are interested in how informal spaces can be used to enhance learning (e.g., museum science) as well as how educators can invite students to make their implicitly learned informal knowledge more explicit in formal educational settings.

Different assessments are more or less likely to tap into variations in each type of knowledge. For example, declarative knowledge is commonly assessed with multiple-choice questions with the assumption that answering correctly means that the learner knows this fact. By contrast, procedural knowledge is assessed as the ability to complete a task (e.g., ride a bicycle, complete a math problem, fly a plane, etc.). Both metacognitive knowledge and epistemic knowledge can be evaluated through self-report surveys (e.g., Mokhtari and Reichard, 2002; Schommer, 1990; Wood and Kardash, 2002), but these aspects of knowledge can also be assessed through interviews, verbal protocol tasks, as well as tasks that require the use of knowledge (McNamara, 2011; Millis et al., 2018).

Dimensions of knowledge

Although the majority of research in knowledge has been on these various types of knowledge described above, more recent work has emphasized the need to more closely examine different *dimensions* of these types of knowledge. The Multidimensional Knowledge in Text Comprehension Framework (MDK-C) Framework (McCarthy and McNamara, 2021) draws from notions of mental model building to argue that prior content knowledge varies along four intersecting dimensions: amount, accuracy, specificity, and coherence. It is of note that the framework was developed with respect to declarative content knowledge, but it is likely that these dimensions are also evident in other types of knowledge.

The **amount** of knowledge refers to the number of concepts in memory. More simply put, this dimension answers the question “how *much* knowledge does the learner have?” Most measures of knowledge in research and education focus on estimating the amount of knowledge across various types of knowledge. Assuming that the items on a knowledge assessment are varied and well-rounded, the score on the test can serve as a relative measure of prior knowledge. That is, students who answer more questions on the knowledge assessment are assumed to know more than those who score less well. However, the MDK-C framework emphasizes that a focus on only how much a learner knows overlooks important other dimensions of that knowledge that can contribute to learning.

A second dimension is the **accuracy** of knowledge. In some philosophical views, knowledge refers only to information that is true in the world. However, more cognitive and education-focused approaches argue that what one “knows” may not be accurate (e.g., vaccines cause autism). Inaccurate knowledge may reflect inaccurate information that was intentionally passed along to the learner (i.e., misinformation, disinformation), but it also includes information that reflects a naive conception that was more implicitly drawn from misunderstanding everyday experiences (Vosniadou and Skopeliti, 2017). In order to measure the accuracy of knowledge, researchers often include distractor items that reflect common misconceptions or naive understandings. A common example of this is in multiple choice math problems. In addition to the correct answer, one of the choices is often a solution that the learner would arrive at if the learner did a procedure out of order. For example, in the problem “ $6 \times 3 = ?$ ”, one of the distractors might be “9.” If a student selects this answer, it suggests that the student might not know arithmetic signs or may not understand the difference between multiplication and addition. Inaccurate knowledge can impair comprehension and learning and can further perpetuate misunderstandings (Kendeou and van den Broek, 2005, 2007; Rapp and Braasch, 2014; van den Broek, 2010). Indeed, inaccurate information can be well embedded in individuals’ knowledge structures, and challenging to overcome or correct (Guzzetti et al., 1992; Vosniadou, 2009). Just like the amount of knowledge, the accuracy of ideas in knowledge is assumed to be on a continuum. Knowledge of ideas may be more or less accurate and the connections between ideas may be more or less accurate. When a learner has many ideas and connections between ideas that contradict known truths, the misconceptions are more challenging to overcome.

The third dimension of knowledge is its **specificity** in relation to the current task. Knowledge about the targeted topic is more specific, whereas general questions about the domain or world knowledge is less specific (e.g., Alexander et al., 1994a,b; McCarthy et al., 2018a,b,c). The specificity of knowledge is not a static feature of the information. That is, a given node in the mental representation is not inherently general or specific, but rather that particular information might be more or less related to the topic at hand. For example, if a student is learning about the digestive system, questions regarding the digestive organs would tap into *topic* specific knowledge. The student may also have subject knowledge about anatomy more generally that may not be immediately relevant to the text, but can support the activation of relevant related information. It may also be important to consider the degree to which the students have more general science (domain) knowledge and also very broad *general* world knowledge as this more distal information can support additional knowledge activation that can facilitate processing as well as the integration and organization of new information.

The fourth dimension of knowledge is **coherence**, which most closely aligns with the notions of structure or organization of knowledge. We borrow the term coherence from theories of text and discourse to highlight the importance of *interconnectedness* of the information in the construction of an elaborated mental model. More connections facilitate knowledge activation, which in turn increases comprehension (e.g., Gernsbacher, 1991; Kintsch, 1988). The importance of coherence is also reflected in theories of expertise which posit that expertise is not defined by mere quantity of knowledge, but rather by how the information is organized

(Alexander, 2004; Bedard and Chi, 1992; Bereiter and Scardamalia, 1986; Langer and Nicolich, 1981; Langer, 1984). Although coherence plays a critical role in learning, many assessments do not include high quality items that can probe for the coherence of the learner's mental model. This is, in part, because assessing the connections between ideas is more complex than measuring whether or not a particular node of information exists in memory. In comprehension tests, researchers often use inference questions to assess the coherence of the learner's mental model. Answers to inference items cannot be found directly in the text. Instead, the reader must connect information from different parts of the text or take the information from the text and apply it to a new scenario. The question "Which cell organelle makes proteins?" asks the learner to search their memory for a particular concept. By contrast, an inference question might ask "What would happen to a cell if there were no ribosomes?" This question is more likely to require the learner to draw upon what they know about the ribosome's function in order to infer what might happen if they were removed. Other methods of evaluating coherence include card sorting tasks (which allow researchers to understand how a learner thinks that different concepts "go together") and evaluating students' open-ended responses (e.g., summaries, explanations, essays) and scoring them for organization or for the completeness or coherence of the written product (see McCarthy et al., 2018c).

The MDK-C framework highlights that these different dimensions of knowledge exist in tandem and depend on one another, with complex interactive effects. For example, broad general knowledge may compensate for a lack of topic-specific knowledge (e.g., McCarthy et al., 2018a) or a coherent, but ultimately inaccurate understanding of a topic (i.e., a misconception) might be more difficult to overcome than a single inaccurate idea among a disparate network of loosely connected ideas (Chi, 2008). Considering multiple dimensions or aspects of knowledge will yield a more complete picture of what a student knows and does not know, and the potential effects on comprehension, learning, and problem solving. Different types of assessment measures are needed to capture the multidimensional nature of knowledge. In turn, more work is needed to better understand how these dimensions manifest across the various types of knowledge (e.g., explicit vs. implicit, declarative vs. procedural, metacognitive, epistemological, disciplinary, formal vs. informal). Considering these four dimensions potentially enhances the ability to more comprehensively evaluate the quality of learners' mental models and make more nuanced predictions regarding how knowledge can or will be used in future tasks.

Building knowledge: acquisition and revision

Assessing what a learner knows before or after a learning activity is only one piece of the puzzle. These assessments serve as formative feedback that can be used to tailor future learning. However, this tailoring can be challenging for educators when they face a classroom of students who each possess varying aspects of prior knowledge or who may have inaccurate knowledge that could impede learning of future content.

Instructors often use lectures or background readings in an attempt to attenuate the effects of students' varying levels of prior knowledge. Essentially, many assume that "giving" students information renders their knowledge of the topic equivalent. However, such an approach is not particularly effective. For example, if a student is provided with background information that is not familiar, then the student must comprehend and learn the new material - it is, in itself, a learning activity: a student with little knowledge of the topic must first learn the information in the text. By contrast, this background reading will serve to activate a knowledgeable readers' existing knowledge base. Thus, while the background reading *may* help a less-knowledgeable reader in the task, the background reading will also facilitate processing and learning from the more knowledgeable reader. Although enhancing learning for all learners is not inherently bad, this approach does not actually "level the playing field" as is usually the intent. Moreover, such an approach can disadvantage students with less knowledge if they do not understand or learn the background material (McNamara and Kintsch, 1996). In lieu of this approach, which leans upon assumptions of *knowledge-as-consumption* and *knowledge-as-deficit*, research in knowledge building and knowledge revision suggests that it is more effective to develop activities and interventions that help learners to leverage and manipulate the knowledge they already possess.

Leveraging existing knowledge

Rather than attempting to quickly introduce new information prior to a lesson, it is more effective to meet the students where they are. This can happen in two ways. The first is by providing individualized scaffolding. For example, students who demonstrate a deep misconception may need to engage in a different task than those who have little understanding of the topic at all. Different activities and interventions may be better suited to particular student profiles. A second complementary way to support learning is helping students to leverage the knowledge that they already possess. This is particularly important because information that exists in memory is not always immediately available, active, or used in a given learning task. Prompting students with more active learning strategies can encourage a deeper search of long-term memory. For example, students with more prior knowledge are more resistant to accepting inaccurate information (Rapp and Braasch, 2014; Richter et al., 2009). Explicitly prompting students to draw upon what they already know by correcting information as they read questionable new content does not fully inoculate them against the inaccurate information, but it can reduce the negative effects (Rapp et al., 2014).

Similarly, tutoring programs such as AutoTutor (Graesser et al., 2004) use questions and hints to help students to bring to bear their existing knowledge. AutoTutor incorporates automated, adaptive hints and prompts that encourage activation of knowledge as well as metacognitive processing, reasoning, and problem-solving strategies. The pedagogical agent moves the student toward the answer, allowing them to generate the solution themselves, rather than giving it to the student.

In addition to specific active learning activities, educators can also help students to learn and effectively use comprehension strategies that facilitate the activation and integration of existing knowledge during learning. For example, interventions like Self-Explanation Reading Training (SERT, McNamara, 2004, 2017) and reciprocal teaching (Palincsar and Brown, 1986; Rosenshine and Meister, 1994) provide instruction and practice to support comprehension strategies such as paraphrasing, predicting, and inference. These strategies encourage learners to try to draw upon their existing prior knowledge to connect information from across different parts of a text and to think about how their current reading relates to things that they already know.

Likewise, iSTART (Interactive Strategy Training for Active Reading and Thinking; McNamara et al., 2004) is an adaptive tutoring system that provides instruction on how to use self-explanation to build upon the knowledge that students have about the topic by using various comprehension strategies. Students learn to paraphrase and self-explain challenging content and then make links, either to prior knowledge or to prior text. iSTART has been shown to be effective across a wide spectrum of learner ages and abilities (Jackson and McNamara, 2013; McCarthy et al., 2018b; McCarthy et al., 2020a,b). Low-knowledge students in particular gain from this type of instruction because they learn that they can use the knowledge that they have to make sense of challenging text (Jackson et al., 2010).

Instructors can also enhance learning by encouraging students to draw upon different types of knowledge. Intervention work shows that having students gesture during learning encourages them to draw upon embodied knowledge that can help them to leverage additional knowledge that they possess about the world (Glenberg et al., 2007; Hostetter and Alibali, 2019; Johnson-Glenberg et al., 2014). Encouraging students to gesture during reading (Glenberg et al., 2011), while solving math equations (Broaders et al., 2007; Cook et al., 2008; Goldin-Meadow et al., 2009), or during science activities (Johnson-Glenberg and Megowan-Romanowicz, 2017) can support deeper understanding and longer retention.

In formal education settings, many students can struggle because of a perceived distinction between “school knowledge” and everyday experience. For example, English Language Arts (ELA) students are often described as lacking the relevant knowledge to engage in discipline-appropriate interpretive reasoning. Levine (2019) argues that the issue is not that students lack this knowledge, but rather educators tend to frame interpretive reasoning as a school-bound, or formal learning activity devoid of connection to everyday experience. This framing prevents students from drawing upon the wealth of knowledge that they have. To demonstrate the potential of “everyday interpretation,” Levine asked students in an ELA course to read a literary short story. In one condition, students were given a common ELA classroom prompt asking about interpretation of themes. Students who were given this prompt tended to struggle with generating interpretations and story-appropriate themes. In another condition, students were asked to complete a sentence stem that encouraged the students to draw on their own everyday experience (“Reading this story suggests that the world can be a place where ...”). These students not only generated more interpretations, but these interpretations were more aligned with the textual information.

Educational research suggests that students are likely to have relevant knowledge that they may not recognize as relevant to the classroom context or to a particular learning task. Educators can help their students bring to bear their own knowledge through activities and prompts that encourage active generation of content that can draw upon multiple types of knowledge. This may involve extended instruction and practice so that students can readily deploy effective learning strategies, but they may also be short prompts or bite-sized changes to the wording of task instructions that can more explicitly guide students to see and use what they already know.

Updating and revising knowledge

It is impossible to learn new information without encountering false information or incorrectly interpreting information. Thus, learning also depends on processes of knowledge updating and revision. Once inaccurate information has been encoded and consolidated in long-term memory, it cannot simply be deleted or replaced (Dole and Sinatra, 1998; Kendeou and O’Brien, 2014). Indeed, researchers in areas of conceptual change argue that positioning learners’ misunderstandings or naive conceptions as misconceptions² that must be replaced, denies both the complexity of knowledge and its constructive nature (Smith et al., 1994). Active generation during learning necessarily includes generating both right and wrong answers, and having incorrect or naive assumptions and understandings. Learning involves gradually developing a coherent understanding of concepts, with the general objective for knowledge to be *accurate*, or aligned with claims asserted by domain experts. Unfortunately, updating and revising knowledge can be challenging.

In the era of “fake news” and misinformation, researchers have been working to understand how we can protect learners from encoding inaccurate information (Rapp et al., 2014; Rapp, 2016). While these steps for preventing inaccurate information from entering long-term memory are important, it is also critical to recognize that not all inaccurate information is derived through direct instruction. Students are not empty vessels; at the least, they bring to the table everyday experiences and observations and informal theories about the world (Carey, 1985). These naive conceptions and experiential knowledge often run counter to scientific explanations (Chinn and Brewer, 1993; Vosniadou and Brewer, 1992, 1994; Vosniadou and Skopeliti, 2017). For example, students experience gravity by seeing objects fall to the ground. These observations lead students to the conclusion that gravity’s force is exerted in an up and down motion along a flat surface. This makes it difficult for students to reckon with the scientific understanding that

²The term “misconception” remains hotly debated (see Vosniadou and Skopeliti, 2017). Researchers also use terms such as “pre-conception,” “naive conception,” “alternative conception” and “misconceived knowledge” to more accurately capture the developmental and often informal nature of this knowledge.

earth's gravity is a centripetal force upon a spherical object. When experience runs counter or slightly askew to scientific explanations, students tend to develop fragmented mental models that allow for maintenance of counterfactuals or they construct coherent, but ultimately inaccurate understandings of the concepts (Disessa et al., 2004). Inaccurate information and mental representations of concepts can render learning more difficult. Discrepant information makes it more difficult to construct a coherent mental model (Alvermann et al., 1985; Kendeou and van den Broek, 2007). Learners can also use their inaccurate information in mental model building, further misdirecting their understanding (Guzzetti et al., 1993; Kendeou and van den Broek, 2005). As this inaccurate understanding becomes more robust, the activation of inaccurate information becomes easier, making it even more challenging to revise the inaccurate nodes and links in the mental model.

A common method of supporting conceptual change is through refutation text (Tippett, 2010; Zengilowski et al., 2021). In refutation texts, the common misconception is mentioned and then immediately refuted with the correct information. Intuitively, it may seem counterproductive to restate incorrect information. However, it is this *co-activation* of information that drives revision. Having both the correct and incorrect information active in memory at once increases the likelihood that the student will recognize and reconcile the discrepancy (Kendeou et al., 2014; van den Broek and Kendeou, 2008). Of course, knowledge revision is not likely to occur in a single instance, but rather refutations offer an opportunity to begin to cultivate a more accurate mental model through additional instruction and support.

Knowledge revision faces further challenges when new information clashes with inaccurate knowledge that is tied to strong attitudes, beliefs, and emotions (Trevors et al., 2017b; Murphy and Mason, 2006; Thacker et al., 2020). For example, students often struggle to understand natural selection because the process is more complicated than common agent-based cause-and-effect relations (Chi et al., 2012; McLure et al., 2020). In addition to the issue of the process itself, ideas of natural selection and evolution are also at odds with many religious beliefs. Attitudes and beliefs tend to bias processing in that students willingly accept attitude-consistent information while rejecting and scrutinizing attitude-inconsistent content (Kunda, 1990; Lord et al., 1979; Maier and Richter, 2013). Beyond topic-specific beliefs, learners' epistemic knowledge and epistemic beliefs about the nature of knowing can also influence the extent to which learners engage with content that is inconsistent with their current understanding (Sinatra et al., 2014; Trevors et al., 2017a,b; Wiley et al., 2020). Interacting with conflicting information can also give rise to negative affective responses which can impede knowledge revision (Trevors et al., 2017b).

These findings suggest that knowledge revision and conceptual change are more complex than simply correcting or replacing individual pieces of inaccurate information. Supporting students' ability to engage in conceptual change and knowledge building requires not only co-activation and updating of declarative knowledge, but also attending to the learners' attitudes and affects and supporting long-term changes in epistemic knowledge and beliefs so that students can develop discipline-appropriate knowledge and epistemologies (e.g., Goldman et al., 2016; Lombardi and Sinatra, 2017). These approaches enable students to build upon their existing knowledge in ways that help them to construct more accurate and coherent mental models.

Implications and conclusions

Helping students to develop their knowledge is the cornerstone of education. However, acquiring knowledge is only beneficial insofar that learners can use that knowledge in new situations. Thus, knowledge is not merely an outcome, but also a key predictor in future learning. Existing research highlights that effective learning comes from capitalizing on what a student already knows and engaging the student in active, knowledge *building*. Learning activities that help students to draw upon the many types of knowledge that they already possess support more meaningful and long-term learning. In addition to understanding the many types of knowledge a learner has, it is also critical to consider multiple dimensions of that knowledge. Such a conceptualization of knowledge further pushes researchers and educators to move beyond diagnoses of the "haves" and "have nots" toward a richer understanding of the nature of what a student knows.

High quality evaluation of knowledge should include summative and formative assessments that tap the multiple types and dimensions of knowledge. It would be impossible to evaluate the whole of a learner's knowledge in a single assessment. Instead, the aim would be to more carefully consider which aspects of knowledge are most clearly related with the current learning task or learning objective and to find or develop measures that align with that knowledge. Through more nuanced understanding of student knowledge, educators can develop instruction and practice that can help their students to more successfully build upon what they already know.

Glossary

Autobiographical memory The sum total of one's memory for one's life makes up one's autobiographical memory. In addition to memory for specific episodes, it contains knowledge of the phases of one's life, of repeated experiences and of pieces of information like telephone numbers and addresses, past and present.

Declarative memory An essential property of declarative memory is that one is conscious of what one is remembering. Such memories are, by their very nature, verbal. For example, one can talk about one's experiences, and about new words that one has learned.

Episodic memory Personal experiences and events are stored in episodic memory (see declarative memory).

False memory A memory that appears real to the person remembering, but is not based on veridical experience is referred to as a false memory. They can be induced in the laboratory, but they are also prevalent in everyday situations, sometimes with drastic legal and interpersonal consequences.

Forgetting It is the inability to recall an episode or a skill that was previously learned. In forgetting of declarative memory (*quod vide*), it is suspected that many failures to recall are in fact due to a failure to access a still-existent memory trace.

Memory systems In contrast to previous schools of thought in psychology, where memory was considered to be unitary, in cognitive psychology one considers memory to be a multifaceted set of modules. There is a host of evidence to suggest that we possess many different types of memory.

[☆]*Change History:* October 2020. The article has been substantially revised and expanded. TJB changed the order of the authors. Opening anecdote about the plot of *The Bourne Identity*, reduced the "Dodo" one. Wrote about Neuroscience and Seductive explanations. SJM wrote about prospective memory, memory training, updated the face recognition paragraph, updated the section on testing in the classroom, and added a description of the [Baddeley \(2012\)](#) study in the section on long-term autobiographical memory. TJB added Autobiographical memory to the Glossary, wrote the Abstract, added a paragraph about number of years spent in education worldwide and the Sustainable Development Goals, rewrote the Memory for People section, updated the False memory section, revised the Dissemination section, and updated the Further Reading. TJB & SM revised according to the feedback, added some relevant recent references, expanded on long-term autobiographical memory.

Nondeclarative memory We are not aware of everything that affects our behavior. These nonconscious effects of previous experience are evidence of nondeclarative memory. Also, our memory for motor skills, such as walking, typing, and skiing, is nondeclarative because motor skills are essentially nonverbal.

Perceptual representation system Conceived of as the interface between perception and memory, it is a basic memory system storing perceptual information that enables us to perceive the world as meaningful.

Priming Things that you have just seen, heard or thought about will facilitate thoughts about related concepts. This expression of memory is referred to as priming.

Semantic memory Believed to be stored separately from personal experiences or episodes, semantic memory refers to a person's general knowledge of the world (see episodic memory).

Working memory A coordinated set of short-term memory mechanisms that allow us to consciously manipulate what we are thinking about at any given moment.

Introduction

Memory is a central part of the brain's attempt to make sense of experience, and to tell coherent stories about it. These tales are all we have of our past, so they are potent determinants of how we view ourselves and what we do. Yet our stories are built from many ingredients. Snippets of what actually happened, thoughts about what might have happened, and beliefs that guide us as we attempt to remember. Our memories are the powerful but fragile products of what we recall from the past, believe about the present, and imagine about the future (Schacter, 1996, p. 308).

The 2002 film *The Bourne Identity* starts with Matt Damon's character being rescued by fishermen off the coast of Marseille. Once aboard it soon transpires that although he can still speak English and several other languages he does not know who he is, how he came to be in the sea, what music he likes, or indeed what his name is. He says "I can read, I can write, I can add, subtract, I can make coffee, I can shuffle cards, I can set up a chessboard" and yet he has no recollection of his prior life. Contrary to what you might think, this Hollywood script is not ridiculously implausible: Conditions similar to Jason Bourne's do in fact crop up. For instance, in January 2003, Dodo, a young man of Asian origin who, in January 2003, woke up outdoors in a small village in Switzerland with a well-equipped rucksack stuffed with expensive clothes and a money belt containing US\$5000, but no identity papers or tickets and with absolutely no personal memory. Dodo wandered around Europe for several weeks, and somehow managed to get to Oslo, Norway. His memory loss of the time before he woke up in Switzerland was massive, he had no idea who he was, and he did not recognize his own face in the mirror. He had even lost his native language – he spoke heavily accented English but not any Asian language; the only things that he knew about himself were that he smoked Camel cigarettes and liked pop music.

Jason Bourne and Dodo suffered from the condition of retrograde amnesia. That is, they lost their memory in the sense people usually use the term, the recollection of private experiences and facts we have learned about the world. But as mentioned, Bourne was still able to draw on past experience in order to read and to shuffle cards, and Dodo knew how to operate photographic equipment and understood the value of money. This type of selective memory impairment is a main argument cited by memory researchers in support of the idea that memory, rather than being a single cognitive process or system, is a collective term for a family of neurocognitive systems that stores information in different formats (Schacter et al., 2000; Tulving, 2002).

Varieties of human memory

Modern taxonomies distinguish between several forms of memory, or memory systems. An important distinction is drawn between declarative memory, which refers to the conscious recollection of facts and personal experiences, and nondeclarative memory, which refers to behavior changes resulting from previous experiences that may or may not be accompanied by conscious recollection (see Fig. 1).

Declarative memory

The story of Dodo illustrates the central role of declarative memory in human life. This young man had lost not only his personal past – his autobiographical memories – but also large parts of his general knowledge of the world and even his ability to speak his native language. Thus, the systems or forms of memory that we term episodic and semantic memory are heavily affected. Episodic memory is assigned a special role in human life: it is unique in the sense that memories are associated with a place and a time, and is, according to Tulving (2002), the only known example of a process where the arrow of time is turned back and the past can be re-experienced. Without episodic memory, the mental representation that psychologists call the self – the organization of personal memories in a historical context – is lost. Obviously, this is what had happened to Dodo though his nondeclarative memory seemed largely intact.

Fig. 1 A common textbook taxonomy of human memory.

Nondeclarative memory

In nondeclarative memory, the effects of previous experiences and actions one has carried out manifest themselves directly in behavior; the individual learning sessions may only be vaguely remembered or even be completely inaccessible to conscious recollection. Procedural memory is responsible for the maintenance of the cognitive and motor skills that we have acquired throughout life, from knowing how to eat with a knife and fork to the mastery of swimming, cycling, or driving a car, as well as the advanced skills of playing billiards or playing a saxophone. Conditioning is a basic memory system that in humans is particularly important in tying emotional reactions to external stimuli or situations. For example, in phobic reactions, anxiety is triggered by the phobic stimuli but the person is typically not aware of the learning episodes in which the connection between the emotion and stimulus was established. Similarly, a piece of music or a specific odor may evoke romantic feelings without an accompanying experienced-memory episode. Perceptual learning, or the perceptual representation system (PRS), enables us to perceive the world as consisting of meaningful entities, because in order to produce a perceptual experience, online sensory signals must reach stored representations. To see is to recognize, or to realize that you do not recognize. [Tulving and Schacter \(1990\)](#) also identified priming as an expression of nondeclarative memory, coupled to the PRS. In priming, the person's performance on a specific task is facilitated (or inhibited) by the previous presentation of related information. For example, perceptual identification of a picture of Melania Trump is speeded by the prior presentation of a picture of Donald Trump, compared to the prior presentation of a picture of, say, Tom Hanks.

An important feature of memory systems is that they store information in different formats, so that the information in one store is not directly translatable into another. However, because the memory systems operate independently and in parallel, most experiences would be recorded and stored in different formats, and an act of remembering would be executed by several memory systems working in concert ([Tulving, 2002](#)).

Short-term memory

Another basic distinction in memory theory is the division between a short-term memory mechanism that is the seat of consciousness and active processing, and which is only able to store limited quantities of information for a limited period of time, and a long-term memory mechanism that stores unlimited amounts of information for unlimited periods of time ([Atkinson and Shiffrin, 1968](#)).

Working memory

A well-developed model of short-term memory is [Baddeley's \(1986, 2003\)](#) concept of working memory, a coordinated set of mechanisms that combine incoming information with information retrieved from long-term memory, assisted by three support systems that actively manipulate verbal, visuo-spatial, and episodic information. The concept of working memory is closely associated with the concept of attention; only those pieces of information that are actively attended to, enter memory. Since the capacity of attention and working memory is limited, it follows that only part of the potentially available information triggering our senses at any one time is registered, and much of the information that is registered is immediately forgotten. In a sense, most of the things we believe we have forgotten, never really entered a durable memory system.

Prospective memory

We usually think of memory as the recollection of things from the past, but in addition to retrospective memory, prospective memory tasks fill our daily lives. Prospective memory involves remembering future events, things we have to do or have planned to do. Some of these memory tasks represent automatic routines, such as turning off the lights when leaving the house; others are one-off events, such as buying theater tickets for the kids' Christmas show. For the latter sort of tasks, many of us nowadays keep some sort of digital diary to remind us to perform the action, but less so for the things that need carrying out daily and it is these

automatic, prospective memory tasks that challenge us in daily life as they are easily interrupted by simultaneously ongoing tasks. Failures of prospective memory may cause severely ill patients to forget to take their medication (Zogg et al., 2012; Avci et al., 2018), and may be responsible for a number of tragic aircraft accidents (Eysenck, 2020a).

Conceptualizing memory and its failures

Metaphors

In the attempt to understand memory, scientists as well as laymen are forced to try to describe something that is not directly observable. We may be aware of some of the processes that take place during learning, and similarly of the processes that take place when we attempt to search for a piece of information in memory, but we have little access to the processes that mediate between encoding and retrieval. In order to make sense of the phenomena to which we have little access, both laymen and researchers tend to use metaphors and analogies, many of which are borrowed from the physical world (Magnussen et al., 2007).

Koriat et al. (2000) pointed out that the study of memory following Ebbinghaus (1885) has been dominated by a storehouse metaphor, in which discrete items of information are stored and later retrieved, and which tends to evaluate memory in terms of the number of items that are retained (or lost). The storehouse metaphor invites an interest in the number of stored items. An effective store is one that contains many items, retains these items for long periods of time, and allows easy access to them. Memory then is evaluated in terms of its quantity – how much is retained, how much is lost. Quantitative aspects of memory are frequently of great interest in everyday life, and research relevant to the classroom and academic achievement typically uses this metaphor.

An alternative approach to the study of memory derives from the correspondence metaphor that can be traced to the work of Bartlett (1932) who had British participants listen to a Native American folk tale called *The War of the Ghosts*. When recalling the story repeatedly over weeks, the memories became shorter, and details dropped out and were replaced by others that were more familiar to the participants; for example, “seal hunt” would be remembered as “fishing expedition” and “canoe” as “boat”. The narratives often became coherent and well-polished, but also unrecognizable as the original. Bartlett’s claim that these results demonstrate the constructive nature of memory is still valid today. In this type of paradigm memory performance is evaluated in terms of the correspondence between the original event and the memory of it: The accuracy of the memory report. A high-quality memory is more faithful to the remembered event than an inferior memory, and contains fewer distortions and errors. Sometimes people remember events that never happened. The assessment of memory correspondence should therefore start with the output – what the person reports – rather than with the input – what actually happened. An output-bound assessment reflects the accuracy of what is remembered – how much of what the person reports did in fact occur (Koriat et al., 2000). In many real-life situations, such as in court, there is much more emphasis on the accuracy of the report than with the amount of information reported.

Factors that make memory inaccurate

The modern study of the accuracy of episodic memory has convincingly disproved another popular metaphor, the idea that our memory is like digital technology where you press “Play” and get the same performance each time. Episodic memory does not reproduce, it constructs, and the reconstruction of previous episodes is based on information from many sources with the assistance of many neural systems (Rubin, 2006). As some of the sources of information used in the construction of episodic memories are external to the original event, memory accuracy suffers. In a widely read book, Schacter (2001) identified seven factors that are behind the tricks that episodic memory plays on us, and called them the “seven sins of memory”. One of the sins is *absent-mindedness*: To be encoded into episodic memory, a piece of information or an event must be attended to. When focal attention is diverted or attention is switched to auto-pilot, information may be missed, and the event is not properly remembered because the information was never registered in the first place. The sin of *transience* refers to fact that memories fade. Some memories fade rapidly, others fade more slowly, depending on a number of factors, but left to itself no memory gets better over time. The general course of memory decay, first described by Ebbinghaus (1885), is the negatively accelerated function shown in Fig. 2A, which represents the long-term forgetting of ordinary life events.

However, as illustrated by Fig. 2B, frequently studied or over-learned material shows very little decay, and some extraordinary life events, in particular dramatic and traumatic experiences, appear to be very resistant to fading and rather obey the sin of *persistence*. In fact, memories we might like to forget can haunt us for the rest of our lives. And sometimes information that we have stored is unavailable to memory because of a failure of retrieval. It feels close – it might be on the tip of your tongue – but the sin of *blocking* renders it temporarily irretrievable. Memories not only fade, they are subject to influences from several sources. The human mind is *suggestible*, our memories of events and facts are influenced by information from external sources, from what we read, and from what other people tell us. Memories are subject to *bias* in various ways. Our memories of the past depend on and are colored by the present. That is, your current attitude to your boss or partner influences how you now recall your feelings about them many years ago. The sin of *misattribution* refers to the confusions and mistakes we often make concerning the source of a particular piece of information, confusions of times, people, and places, and in the extreme case, the confusion of genuine memory and fantasy that gives rise to false memories.

Fig. 2 (A) Memory for personally experienced everyday events, Wagenaar (1986) plotted with triangles and White (2002) plotted with squares. (B) Very long-term memory for over-learned material, obtained by asking participants to match pictures of high-school classmates “faces to their names, (circles), and testing participants’ ability to translate unused Spanish vocabulary learned in school to English, (squares). Despite the fact that we treasure our autobiographical memories and they play an integral role in our personal identity, we become incapable of bringing to mind the specifics of most of what we experience within a year or so of it happening. By contrast, multiple repeated exposures to something that is quite unimportant for one in later life and never practiced or recalled can allow access to memories decades later. This may be seen as paradoxical until one realizes that motivation to remember is not always as important as the amount of practice one has put in to learning something. (A) Adapted from Wagenaar, W., 1986. My memory: a study of autobiographical memory over six years. *Cognit. Psychol.* 18, 225–252; White, R., 2002. Memory for events after twenty years. *Appl. Cognit. Psychol.* 16, 603–612. (B) Adapted from Bahrnick, H.P., Bahrnick, P.O., Wittlinger, R.P., 1975. Fifty years of memories for names and faces: a cross-sectional approach. *J. Exp. Psychol. False autobiographical memories

In the 1990s, the science of memory was the subject of a fierce debate in scientific journals, newspapers, and courts of law. A phenomenon that was first observed in the United States but that has since spread to other countries is that cases of alleged child abuse were being brought to court by the victims, years and even decades later, because the victims had previously been unable to retrieve the memories. This was a powerful and deeply shocking claim that split psychology into those who thought of these memories as recovered, and those who thought of them as false, the so-called memory wars.

Since Bartlett’s seminal research on how our memory for narrative introduces errors that fit in with the rest of our knowledge, researchers have known about the malleability of our memories for events. Due to the memory wars, such memory illusions have been much studied over the past decade, showing that under certain circumstances, we can become convinced that, several years previously, one had been up in a hot air balloon, or had knocked over a punch bowl at a wedding when these events simply had not happened (Loftus, 2003). The key ingredients appear to be that one believes the authority telling one the information, and that one is given time to try to retrieve the information: over time, the false memories come to feel real to the person remembering. There is then a danger in the therapy situation where a clinician meets a patient, if the clinician believes that symptoms of depression and anxiety are in fact the manifestation of experienced child abuse that the patient has forgotten. There are documented cases where entirely false accounts of abuse have been induced in patients. These “recovered memories” may be highly implausible but nevertheless genuinely believed by the patient. They are produced by the combination of an authority figure, in this case the therapist, and several practice sessions in which the patient tries to “recover” the memories. A number of documented cases show that false memories may be quite dramatic, as for example, remembering being witness to a murder that never happened (Goodman et al., 2007). Modern research also fails to support the idea that early traumatic childhood experiences can be stored in a detailed fashion but repressed or blocked from consciousness, only later to be exhumed by therapeutic exercises. Rather, well-controlled studies show that such memories obey the sin of persistence (Goodman et al., 2003).

Knowledge of the constructive nature of autobiographical memory is important for many professions, especially those dealing with psychiatric patients, children, and other groups with little power. The vulnerability of autobiographical or episodic memory is also the focus of another important area of applied memory research, the study of factors affecting the reliability of eyewitness testimony (Howe and Knott, 2015). In the interrogation room and in court, failures to remember are less damaging to the judicial process than are memory errors; absence of memory points nowhere, memory errors may point in the wrong direction.

In memory implantation experiments it is challenging for researchers to reliably categorize participants as having experienced a false memory or not. Different ways of coding the data give different estimates of what proportion of participants fully accepted the false memory (Brewin and Andrews, 2017; Scoboria et al., 2017). However, even those researchers urging caution accept that a nontrivial proportion do end up convinced that the false event in fact occurred.

Memory in everyday contexts

Ebbinghaus (1885) pioneering studies investigated his own memory for nonsense syllables, and a century later, as cognitive psychology became the dominant school in psychology in the 1970s, the typical experiment on memory still clearly bore Ebbinghaus' imprint: university undergraduates sat in a darkened lab and learned long lists of words. A degree of discomfort with the potential lack of relevance of these experiments for understanding life outside the lab, led to a push for memory research to be more ecologically valid, and the study of applied memory has since grown into a very active research field. Drawing on the correspondence metaphor of memory, a key underlying question in this field has been how accurate our memory is, as it is used in everyday life. Another change has been in the types of material used: breaking out of the verbal learning tradition (learning lists of words), a concerted research effort over the past 30 years has, for instance, tried to shed light on our ability to remember more real-life stimuli, like people, and events we have experienced in our lives (a skill that Dodo apparently no longer possesses).

Memory for people

A person represents an extremely complex and multifaceted biological stimulus: While we often recognize a person from their face, we can also judge who a person is from their name, their voice, their gait, besides many other potential routes. Not all types of person information are equally memorable. People sometimes say "I forget names but never faces"; the scientific literature shows that while the first part of the claim is likely to be true, the second is only partly so. People's names do pose a problem when it comes to recall. All readers will have experienced the tip-of-the-tongue phenomenon for a name, when one is unable to recall a name but feels that one might recall it at any time, and may be able to give partial information about the missing word. This phenomenon occurs particularly for people's names, and its frequency increases with age (Valentine et al., 1996).

When it comes to remembering faces, it is true that we have good memory for people we have spent lots of time with or frequently viewed in public media. Humans are social animals heavily reliant on vision and there is a strong need to distinguish between family, friends, and enemies, for instance. However, our memory for faces that we have only seen once is very poor. For briefly-viewed unfamiliar faces, there is little evidence of any memory after one year (Deffenbacher et al., 2008). Even comparing a briefly-seen face to a series of pictures taken the same day yields 10% errors, and when the line-up pictures were taken 3 months previously 30% of the identifications were incorrect (Megreya et al., 2013). Thus we are not gifted at matching a person to their photo ID (which may have been taken several years previously), and indeed shop assistants are terrible at detecting that the face on the card does not match the person proffering the card (Kemp et al., 1997). Similarly, this work raises questions about how reliable lineup identifications are in criminal cases. The evidence suggests they are indeed not very good; results from a recent analysis of lineups showed that about 30% of the identifications by witnesses are of a person in the lineup who is known to be innocent (Wells et al., 2020).

Long-term autobiographical memory

How much of our lives do we remember? Cognitive psychologists tend to agree with the sentiments of the novelist Milan Kundera (2002) who pointed out that in fact we are only able to recall a vanishingly small proportion of the events in our lives. While we do of course remember many individual events from our lives, much of our autobiographical memory appears to be based on generalized averages of similar events, so that while you may only be able to specifically recall a few of the times you have been to the Odeon cinema, you may know very well where you usually park, what sort of films you see, who you go with, and what snacks you buy. A systematic approach to answering the question was taken by Wagenaar (1986) who wrote down one incident from his life each day over a period of 4 years. When subsequently tested, he found that being cued by the who, what, or where of an event was more powerful a cue than when, and that a single piece of information (who, what, or where) triggered recall of the incident on only about 50% of occasions for the first year and declined to 20% after 4 years. Multiple cues triggered over 60% of memories, even after 4 years, and even cases where he had apparently forgotten the incident completely could be recalled when the event involved another person who could be asked to provide more cues. Thus, it is a case of the glass being half-full or half-empty: Even events which were thought to be completely forgotten turned out to be retrievable, but on the other hand, normal cues failed to trigger a majority of memories. Results from Wagenaar's (1986) report together with results from a similar study carried out across a 20-year interval by White (2002) are shown in Fig. 2A and illustrate the dramatic decline of ordinary everyday memories. White (2002) tested his memory by having an assistant read event descriptions picked randomly, and he decided if he remembered the event vividly, vaguely, or not at all. Most of the remembered events were only vaguely remembered, and he encountered not a single case where an event forgotten at one point in time was later remembered.

Do we eventually forget almost everything from our past? Of course not. These studies tested memory for isolated events, short episodes that were not embedded in a broader context. But autobiographical memory - what we remember from our lives - is more than a collection of isolated events. We remember events integrated as part of more extended memory schemata that form our coherent life story and concept of self (Courage and Howe, 2010). Episodes are understood and remembered in the context of longer life periods, which can last for several years and tend to be personally significant, such as our years in college, our romantic relationship(s), holidays abroad and professional positions. White also kept a diary from January 1978 to December 1980 when he among other things worked temporarily at another university and participated in several scientific conferences, and found that, forty years after the original events, he spontaneously remembered a lot of events and single episodes when cued by these extended

events. On the other hand, reminiscent of the question of the glass being half-full or half-empty mentioned above, two-thirds of the events he remembered 20 years after they occurred were unavailable 40 years after (White, 2020).

In 2012 Alan Baddeley, a major figure in memory research, performed an informal test of his own autobiographical long-term memory via letters sent to his mother during a year spent in the US 40 years previously. Already known as a prolific writer, we thereby discovered that he was also a devoted son, and because his mother kept the letters it was possible to identify events from his distant past. Of 62 episodes he was able to remember 23, but only half of them vividly. It may sound disappointing that only 20% of our past is remembered, but, as suggested by Kundera, the truth may be even more sobering: These long-term studies may vastly overestimate our everyday memory performance for two reasons. Firstly, the selection of episodes to be remembered is probably not random so that trivial events such as “I had Chinese take-away for supper” are unlikely to be recorded and secondly the memory is strengthened by the very fact that it is chosen and written down. Classical studies where participants are required to record what they are doing at random intervals have shown that only one-fifth of such episodes are remembered after six weeks, which may also be an overestimation due to the rehearsal effect. Our memory for details of daily events and episodes is even worse. In a recent study (Misra et al., 2018), participants wearing a head-mounted camera and eye-view recorder walked a pre-determined route in a city for about an hour. Their memory for the walk was tested a day later by having the participant choose between 2-s recordings of their own walk and walks through the same route by other participants, who met other people, other cars, and walked under different light conditions. The results showed that participants scored close to chance. Most of the details we experience in daily life disappear very quickly indeed.

Memory training

Can memory be trained? This is a hot topic, and quick-fix courses flourish in the popular media. Is it possible through mental exercises to increase one's memory capacity and make your memory performance more reliable or even spectacular? The answer is both yes and no. There are well-known ancient memory techniques that are effective for most of us when trying to remember things such as a shopping list or the names of a new group of people, and memory experts who excel on memory tasks that require the repetition of vast numbers of single items rely on such techniques. It has been known for many years, however, that the effects of memory training are restricted to the tasks one has spent time perfecting (typically list learning) or very similar tasks, with little or no transfer to memory performance in general (De Beni et al., 2007). Thus, practicing learning of word or digit lists does not make you better at remembering books you read or events you have witnessed: There is no way of enhancing your general memory performance (Eysenck, 2020b).

Memory in the classroom

The vast majority of children in the West spend upwards of a decade of their lives going to school. Sadly, on the poorer continents many children, especially girls, spend fewer years than this in formal schooling. In Niger, which in 2018 was the lowest ranked country on the Human Development Indices and Indicators, a child can only expect to spend five years in school (UNDP, 2019). The UN's fourth Sustainable Development Goal is to “Ensure inclusive and equitable quality education and promote life-long learning opportunities for all”. Delivering a quality education includes documenting that pupils have managed to learn, and memory science can be a source of advice as to how to achieve this.

Testing improves retention

It might be surprising to some that a body of evidence has built up recently to suggest that the best way to study for a test is to test oneself. For instance, Roediger and Karpicke (2006) asked participants to read and learn a short essay. After all participants had read the passage through, one group was then given a test on what they had remembered, whereas the other group reread the passage. There was then a final memory test given, either 5 min, 2 days, or a week subsequent to the reading. After 5 min, those participants who had reread the passage performed better than the other group. However those tested after 2 days and those tested after a week showed the opposite pattern: an extra opportunity to study the material led to worse memory compared to those who were tested in the first phase (see Fig. 3).

The testing effect has proved to be very robust, confirmed by a number of subsequent studies conducted in the laboratory (Rowland, 2014) and real-life contexts (Schwieren et al., 2017), as well as by a recent review (Yang et al., 2021). The message from this literature is clear: the very act of testing improves performance. It is to be hoped that educational systems will confront the challenge to incorporate the consequences of this finding into their classrooms: testing is not only a way of assessing students' performance, it also a way of facilitating their learning.

Long-term retention of knowledge from school

How much of the knowledge one acquires in school becomes lifelong? One of the secrets to creating robust long-term memories, known to science since at least the 19th century and known to centuries of teachers, is repetition or over-learning. Schoolchildren spend a lot of time in classrooms learning from teachers, books and digital media, but the exams that test if the requisite knowledge

Fig. 3 Having heard a story they were trying to learn, some participants were immediately tested on what they could recall, while others had a second chance to learn the story. Five minutes later, the second-chance group (*the dark column*) had better recall, but of potential importance to educationalists, the immediate-test group (*the light column*) did better on tests 2 and 7 days later. Adapted from Roediger, H.L., Karpicke, J.D., 2006. Test-enhanced learning – taking memory tests improves long-term retention. *Psychol. Sci.* 17, 249–255.

has been acquired usually take place within a few months of the teaching, which begs the question of the fate of this knowledge in the long term. How much of the Spanish vocabulary that you learned in high school can you still recall? What about the fate of your university degree that you haven't used since your graduation exams? Seminal research by Harry Bahrick has shown that we are able to recall surprising amounts of knowledge even several decades after learning (see for example, [Bahrick, 1984](#)). Lots of material seems to become unavailable within the first year of learning. About 2 years after studying a topic, people are able to perform at around 50% of the level they were at when they stopped studying, but the surprising finding is that up to 50 years later, one performs at about the same level as one did 2 years after: very little forgetting appears to occur after an initial period. Similar results have been reported for mathematics, Spanish, and for cognitive psychology, so that this function appears to reflect general properties of the long-term semantic memory system, or *permastore* as Bahrick termed it (see [Fig. 2B](#)).

The future of memory science

Memory research finds itself at a touchpoint between basic and applied research. It is becoming more integrated into neuroscience, with studies using cognitive tasks in conjunction with brain imaging methods, in particular functional magnetic resonance imaging (fMRI) techniques, by which brain processes may be visualized online concurrently with ongoing cognitive tasks. Has this integration of memory research and fMRI advanced our understanding of memory?

Cognitive neuroscience

While brain science still holds the promise of one day providing an integrated multilevel account of memory function that is applicable in practical contexts like schools, the current stage of cognitive neuroscience is rather distant from this. On a pessimistic view, it is somewhat bound by its laboratory methods where, typically, participants are placed in physically restricting postures performing esoteric yet trivial intellectual tasks; small effects are observed in complex patterns of data, the interpretations of which have almost limitless degrees of freedom, and which invariably end up confirming the original cognitive research anyway. These challenges come in addition to the finding that frequently-used brain scanning measures have low reliability ([Elliott et al., 2020](#)).

The seductive allure of neuroscience explanations

This would perhaps not need pointing out were it not for the generally overoptimistic attitudes to neuroscience in society at large, referred to as the “Seductive Allure of Neuroscience Explanations” ([Weisberg et al., 2008](#)). In 2014, a large number of psychologists and neuroscientists signed a document decrying the claims of the “brain training industry” which, for a fee, promises to increase your IQ or to stave off dementia by means of some sessions of concentrated practice on some cognitive tasks ([A Consensus on the Brain Training Industry from the Scientific Community, 2014](#)). Another reason for a sober approach to the ability of neuroscience to deliver is the effect reported by Weisberg et al. showing that when judging how good explanations of psychological phenomena are, nonexperts mistakenly give positive weight to irrelevant neuroscientific information. [Im et al. \(2017\)](#) demonstrated the same effect when members of the public read articles about educational issues; in particular, they found that articles were rated as more credible when the spurious neuroscience information was accompanied by a picture of a brain.

Dissemination and implementation of the established science

On the other hand, a reason for optimism is that the emphasis on an understanding of memory in everyday contexts is strengthening. This is a welcome development because the focus in recent decades on more applied sides of memory – how it is actually used in daily settings – has produced results with important real-world implications. For all in the legal system, from the police to judges to jury members, the literature showing the fallibility of eyewitnesses' memory for people and events should be required reading. The application of the findings from the field of memory (and cognitive psychology more generally) to educational settings is beset with controversy (see for example Claxton, 2021). Regardless of one's position on, for example, the dichotomy between "progressive" and "traditional" teaching methods, one would hope that educational planners have, in addition to specific knowledge about phenomena like the positive gains obtained by the very act of testing someone's knowledge, an appreciation of the limits and character of memory.

Problem solving is frequently in the spotlight of educational reform, particularly in light of calls for graduates to be able to be innovative (Pelligrino and Hilton, 2012). In addition to remembering information, students must be able to use what they have learned to solve new problems. A major goal of education is to help students become effective problem solvers, that is, people who can generate useful and original solutions when they are confronted with problems they have never seen before. This entry examines aspects of the large body of research on problem solving (Ball and Thompson, 2019; Holyoak and Morrison, 2012; Mayer, 1992) that are most relevant for education.

Definitions

A *problem* consists of a given state (i.e., a description of the current situation), a goal state (i.e., a description of the desired situation), and a set of operators (i.e., rules for moving from one state to another). A problem occurs when a situation is in one state, the problem solver wants it to be in another state, and there are obstacles preventing a smooth transition from the given state to the goal state. Duncker (1945: 1) defined a problem in the following way: “A problem arises when a living creature has a goal but does not know how this goal is to be reached.” Although Duncker’s definition is still valid, it must be updated to include the possibility of problem solving by machines, and so the term problem solver can refer to both living creatures and machines.

Problem solving occurs when a problem solver engages in cognitive activity aimed at overcoming a problem. Duncker (1945: 1) noted that “when one cannot go from the given situation to the desired situation simply by action, then there has to recourse to thinking” and “such thinking has the task of devising some action which may mediate between the existing and desired situations.” Similarly, Polya (1981: ix) defined problem solving as “finding a way out of a difficulty, a way around an obstacle.” In developing computer simulations of problem solving, Newell and Simon (1972) defined problem solving as a search for a path between the given and goal states of a problem. Mayer (1992) summarized three major elements in a definition of problem solving: (1) problem solving is cognitive because it occurs internally within the problem solver’s cognitive system, (2) problem solving is a process, because it involves manipulating or performing operations on the problem solver’s cognitive representations, and (3) problem solving is directed, because the problem solver is attempting to achieve some goal. In short, problem solving is directed, cognitive processing aimed at finding a way to achieve a goal.

What is the relation between problem solving and other high-level cognitive processes such as thinking and reasoning? Thinking can be broken down into two types—directed and nondirected thinking. Problem solving is a common and pervasive type of thinking, namely, directed thinking in which the thinker engages in cognitive processing aimed at achieving some goal. On the contrary, in nondirected thinking, the thinker engages in cognitive processing that is not aimed at achieving some goal, such as day-dreaming or the abnormal thinking of people with schizophrenia. In general, the terms problem solving and thinking can be used interchangeably, with the recognition that nondirected thinking is excluded.

Reasoning can be viewed as a type of problem solving that involves inference in deductive reasoning tasks and inductive reasoning tasks. In deductive reasoning, the problem solver is given premises and must apply the rules of logic to derive a conclusion. For example, if you know all four-sided polygons are quadrilaterals and all squares are four-sided polygons, you may logically conclude, all squares are quadrilaterals. In inductive reasoning, the problem solver is given a series of instances or events or examples and must infer a rule. For example, after learning the Spanish words *la casa*, *el libro*, *la escuela*, *el perro*, *la muchacha*, and *el muchacho*, you may conclude that the article *la* goes with words ending in *a* and the *el* goes with words ending in *o*, a grammatical rule that is not without exceptions in Spanish.

Creative thinking occurs when a problem solver generates ideas and critical thinking occurs when a problem solver evaluates them. Two important criteria in creative and critical thinking are that the ideas must be original and useful.

Finally, intelligence is sometimes defined as the ability to adapt to new situations or, more simply, as the ability to learn (Hunt, 2010; Sternberg, 2020). Viewed in this way, individual differences in intelligence can be considered as individual differences in the ability to engage in problem solving.

Types of problems

An important distinction—based on the clarity of the problem statement—can be made between well-defined problems and ill-defined problems. A well-defined problem has a clear given state, a clear goal state, and a clear set of allowable operators. For example, finding the value of x in an algebraic equation such as $2X + 5 = 8$ is a well-defined problem because the given state is the equation, the goal state is a value for $X = \underline{\hspace{1cm}}$, and the operators are defined by the rules of algebra and arithmetic. In contrast, an ill-defined problem has a poorly specified given state, goal state, and/or operators. For example, choosing an appropriate education for a career path is an ill-defined problem because the goal and allowable operators are not clearly specified. Most problems encountered in school are well-defined problems, whereas most crucial problems in everyday life are ill-defined.

Another important distinction—based on the knowledge of the problem solver—can be made between routine and nonroutine problems. Routine problems are identical or very similar to problems that the problem solver already knows how to solve, and therefore require what Wertheimer (1959) called *reproductive thinking*—reproducing responses that have been produced previously. For example, a routine problem for most high school students is “ $55 \times 5 = \underline{\hspace{1cm}}$ ”. In the strictest sense, routine problems do not conform to the definition of problem, since they do not include an obstacle between the given and goal states. In contrast, nonroutine problems are different from problems that the problem solver already knows how to solve and therefore require what Wertheimer (1959) called *productive thinking*—creating a novel solution. Examples for most high school students include writing a computer program to compute the mean and standard deviation of a sample, or writing a short essay answer on why Spanish explorers waited several centuries before colonizing California. In school, students often work on routine problems called exercises; however, most important problems in everyday life are nonroutine.

A third distinction can be made between problems requiring convergent and divergent thinking. Convergent thinking problems have a single correct answer that can be determined by applying a procedure or retrieving a fact from memory. Examples include arithmetic computation problems. Divergent thinking problems have many possible answers, and so the problem solver’s job is to create as many solutions as possible (Guilford, 1967). Classic examples include uses problems, such as “List all the possible uses of a brick,” and consequences problems, such as “List all the consequences of humans having six rather than five fingers.” Creativity can be measured in terms of the originality and usefulness of the answers, and divergent thinking skills, which underlie creativity, are taught in courses on creative thinking (Kaufman and Sternberg, 2019; Kaufman et al., 2017). Although divergent thinking is regarded as the hallmark of creativity, solving insight problems (i.e., problems that require devising a novel solution method) has been found to be most strongly related to convergent thinking (Webb et al., 2017).

Cognitive processes and types of knowledge in problem solving

Problem solving can be divided into two major phases: problem representation and problem solution. Problem representation involves building a mental representation of the problem, and includes the cognitive process of representing (i.e., building a situation model, that is, a mental representation of the situation described in the problem). Problem solution involves devising and carrying out a plan for solving the problem, and includes the cognitive processes of planning (i.e., devising a plan), executing (i.e., carrying out the plan), and monitoring (i.e., tracking the effectiveness of the plan).

The cognitive processes involved in problem representation and problem solution may interact, rather than occur in linear order. For example, a student may be given the following word problem: “Sarah has three marbles. David has two more marbles than Sarah. How many marbles does David have?” In representing the problem, the student must translate each sentence into an internal mental representation, such as “Sarah’s marbles = 3” and “David’s marbles = Sarah’s marbles + 2,” and mentally integrate them into a situation model, such as a spatial representation consisting of a bar for Sarah’s marbles (3 units high), a bar on top of it for the difference between Sarah’s and David’s marbles (2 units high), and a bar next to these for David’s marbles (indicating that Sarah’s marbles and the difference set of marbles are subsets of David’s marbles). Planning involves determining the operations to be performed, such as determining that 3 and 2 must be added together. Executing involves carrying out the operation(s), such as computing that 5 is the sum of 3 and 2. Monitoring involves detecting when a plan is not working, a step was not executed correctly, or an answer is questionable. Although school instruction tends to emphasize execution of basic skills, students’ major difficulties are in learning how to represent problems, devise plans, and monitor problem-solving processes.

Several types of knowledge are required for successful problem solving: facts, concepts, procedures, strategies, and beliefs (Anderson et al., 2001; Mayer, 2011). Facts are elements of a factual knowledge about the world, such as, “There are 1000 mL in a liter.” Concepts are principles or models (which are elements of conceptual knowledge) such as, “In the number 567, 6 refers to the number of tens,” or categories or schemas (which are elements of schematic knowledge), such as knowing that “What is the probability of flipping a fair coin three times and getting heads all three times?” is a joint probability problem. Procedures are step-

by-step processes, such as knowledge of the procedure for long division used for 252 divided by 12. Strategies are general methods for problem solving, such as knowing how to break a problem into smaller parts. Meta-strategies are methods for controlling and adjusting the use of all the five kinds of knowledge during a task. Beliefs are thoughts about one's cognitive processing, such as believing, "I am good at solving statistics problems." Facts and concepts are useful in the process of representing; procedures are useful for the process of executing; and strategies and beliefs are useful for planning and monitoring. Although instruction may tend to emphasize facts and procedures, all five kinds of knowledge are needed to support problem solving. This means that problem solving can depend on having learned appropriate knowledge.

Rigidity in thinking

A major obstacle to effective problem solving is rigidity in thinking. For example, in some problem-solving situations, the problem solver must use an object in a new way, such as using a brick as a doorstop or using a pencil as a bookmark. When a problem solver can only conceive of using an object in its most common function, then the problem cannot be solved. Duncker (1945) used the term *functional fixedness* to refer to a situation in which a problem solver cannot think of using an object in a new function that is required to solve the problem. Another example of rigidity occurs when a problem solver uses a well-learned procedure on a problem for which the procedure is inappropriate. For example, if a student solved a long series of arithmetic story problems that all contain the word "more" and require adding the numbers together, the student may incorrectly carry out this same addition procedure for a new problem that actually requires subtracting the numbers from one another. Luchins (1942) used the term *Einstellung* (or problem-solving set) to refer to this phenomenon. A goal of instruction in problem solving is to help students avoid rigid thinking.

Problem-solving transfer

Transfer is the effect of prior learning on new learning. When the new learning task is a problem to solve, we can use the term problem-solving transfer to refer to the effect of prior learning on solving a new problem (Mayer and Wittrock, 2006). Positive transfer occurs when previous learning helps you on a new task, whereas negative transfer occurs when previous learning hurts you on a new task. For example, if you have automated your use of arithmetic procedures, this should make it easier for you to solve an arithmetic word problem—which would indicate positive transfer. If you learned to drive on the right side of the road in the United States, you may experience negative transfer in trying to learn to drive on the left side of the road in Australia.

How does transfer work? This has been a central research question in psychology and education since Thorndike's (1931; Thorndike and Woodworth, 1901) pioneering work in the early 1900s, and has generated three alternative explanations: *general transfer*, *specific transfer*, and *mixed transfer*. General transfer is the idea that learning task *A* can help you on task *B*, even if *A* and *B* have nothing specifically in common. For example, the doctrine of formal discipline (which is a classic theory of general transfer) posited that learning certain school subjects, such as Latin and geometry, would improve students' minds in general and thereby help them on unrelated tasks in the future. The doctrine of formal discipline was used to justify the establishment of Latin schools, in which the curriculum consisted of learning Latin, Greek, geometry, and similar subjects. In one of the first experiments in the field of educational psychology, Thorndike (1931; Thorndike and Woodworth, 1901) was able to show that students who learned Latin did not perform any better in learning bookkeeping than did students who had not learned Latin. Subsequent research (Singley and Anderson, 1989) also found little support for the idea of general transfer. In short, learning to be a good problem solver may require different kinds of training for each academic discipline or subject area.

In contrast, specific transfer is the idea that learning task *A* will help you in task *B* only to the degree that *A* and *B* have identical elements in common. Thus, learning Latin may help you learn Spanish because some of the verb conjugations are similar and many of the words are similar. The theory of specific transfer is problematic for educators because it suggests that students need to learn every specific piece of knowledge they will ever need.

Mixed transfer is a compromise between general and specific transfer that involves specific transfer of a general principle, that is, mixed transfer occurs when a learner abstracts a general principle from learning *A* and is able to apply it to solving a new problem *B*. The transfer is specific because both *A* and *B* can be solved by the same general principle but what is being transferred is a general principle rather than specific behaviors. For example, if students learn to make sense out of text passages by producing summaries, this general method can be transferred to the task of making sense out of a new text passage. Research on teaching of cognitive strategies shows that students can benefit from learning general strategies such as summarizing in reading comprehension (Fiorella and Mayer, 2015). The implication for education is to focus on general principles, concepts, and models that can transfer from one situation that requires the principle to another, such as a mental number line for understanding addition and subtraction or the nature of air pressure for answering questions about how a tire pump works.

Promoting positive transfer is a fundamental goal of education, that is, educators seek to help students learn in ways so that they will be able to use what they have learned to solve new problems. Mayer and Wittrock (2006) have described seven ways to promote problem-solving transfer: load-reducing methods, such as helping students build automaticity in basic skills; structure-based methods, such as using concrete models; schema-based methods, such as using advance organizers or pre-training; generative methods, such as encouraging learners to engage in elaboration or self-explanation; guided discovery methods, such as providing

hints as someone solves a problem; modeling methods, such as providing worked examples; and teaching thinking skills, such as training people to use effective methods and strategies.

The distinction between productive and reproductive thinking

Why is it that some people invent clever solutions when confronted with a problem, whereas others do not? The Gestalt psychologist, [Wertheimer \(1959\)](#) attempted to answer this question by distinguishing between two kinds of thinking: *productive thinking* and *reproductive thinking*. Productive thinking involves producing a novel solution when confronted with a problem, whereas reproductive thinking occurs when problem solvers use solution procedures that they already know as a result of solving previous problems.

For example, [Wertheimer \(1959\)](#) described two ways of learning how to find the area of a parallelogram—*learning by rote* and *learning by understanding*. In learning by rote (or rote learning), the student is taught to measure the height, measure the base, and then multiply height times base. According to Wertheimer, students who learn by rote perform well on retention tests, such as finding the area of similar parallelograms, and poorly on transfer problems, such as finding the area of an unusually shaped parallelogram. In contrast, students who learn by understanding (or by meaningful learning) are encouraged to discover that the parallelogram can be converted into a rectangle by cutting the triangle off one end and moving it to the other end. Students who learn by understanding are expected to perform well on both retention and transfer tests. Thus, rote learning leads to reproductive thinking (as measured by retention tests) whereas meaningful learning leads to productive thinking (as measured by transfer tests). Most educators seek to develop students who can engage in productive thinking, although there is a place for reproductive thinking when students can automate common tasks such as how to make arithmetic computations.

The nature of insight

Insight is the cognitive process by which a problem solver suddenly moves from a state of not knowing how to solve a problem to a state of knowing how to solve a problem ([Mayer, 1995](#); [van Steenburgh et al., 2012](#)). Insight plays a crucial role in creative thinking ([Kaufman and Sternberg, 2019](#)), in which a problem solver invents novel solutions to a problem. How does insight work? Gestalt psychologists and others have offered five somewhat interrelated explanations ([Mayer, 1995](#)): insight as completing a schema, insight as sudden visual reorganization, insight as reformulation of a problem, insight as removing mental blocks, and insight as finding a problem analog. Selz, working in the early 1900s in the Netherlands, produced psychology's first explanation of insight as completing a schema ([Frijda and De Groot, 1982](#)). For example, when given a problem such as "What is a co-ordinate of baseball?" a problem solver may say, "Let's see. Baseball is a sport. Another sport is football, so football is the answer." In this case, the problem solver is not following a chain of associations, but rather is trying to build a cognitive structure that has a superset (sport) linked to two subsets that are co-ordinates (baseball and one more), so coming up with an answer amounts to completing a schema. The idea that meaningful learning requires active construction by the learner is the fundamental theme of many current theories of academic learning ([Mayer, 2011, 2014a](#)).

Kohler, also working in the early 1900s, provided evidence that insight is a process of sudden visual reorganization in which the problem solver literally sees how all the parts of the problem fit together ([Kohler, 1925](#)). For example, when an ape was put in an area that had stackable crates on the floor and bananas hanging overhead out of reach, the ape looked around and then in an apparent flash of insight, suddenly stacked the crates to form a sort of ladder leading to the bananas. This approach is consistent with current interest in using computer-assisted visualizations and concrete representations to help people understand how various systems work ([Mayer, 2020](#)).

[Duncker \(1945\)](#) described insight as a reformulation of the problem, particularly a restatement of the givens or the goal in a new way. For example, in the tumor problem, you are asked to free a person of an inoperable stomach tumor by using "rays which destroy organic tissue at sufficient intensity" (p. 1). In order to solve the problem, the problem solver must restate the goal as, "lower the intensity of the rays as they pass through the healthy tissue," which leads to the solution of having many weak rays all converge on the tumor. This approach is consistent with the current idea that the most difficult aspect of problem solving is mentally representing the problem in a productive way.

[Duncker \(1945\)](#) also described insight as a process of removing mental blocks, that is, of being able to use an object in way that is different from its conventional use. For example, in the candle problem, the problem solver is given a box containing candles, a box containing tacks, and a box containing matches, and is asked to mount a lighted candle on a wall. The solution—involving using a box as the base, which is tacked into the wall—is much more difficult if the objects are in the boxes rather than next to them. According to Duncker, presenting the objects in the boxes creates functional fixedness—the tendency to be able to conceive of only one use of an object even though a problem solution requires using an object in a new way. Removing mental blocks is a key focus of current programs aimed at teaching thinking skills ([Behar-Horenstein and Niu, 2011](#); [Wegerif et al., 2015](#)).

Finally, [Wertheimer \(1959\)](#) offered a fifth explanation of insight—finding a problem analog—in which the problem solver abstracts a general principle from one problem and applies it to a new one. Thinking by analogy is still an important theme in cognitive science, and is the basis for more current views of problem-solving transfer ([Holyoak, 2012](#)).

A sixth explanation—insight as nothing new—holds that solving insight problems is no different from solving other problems (Weisberg and Suls, 1973), although Metcalfe and Wiebe (1987) have shown that problem solvers use qualitatively different thinking processes for insight problems and routine problems. More recently, Chuderski and Jastrzebski (2018) reported that solving insight problems was highly correlated to measures of working memory, so that “little above and beyond WM is unique about insight” (p. 257).

Problem space and search processes

Information-processing theories of problem solving focus on constructing a problem space and finding a path through the problem space (Newell and Simon, 1972; Novick and Bassok, 2005). A problem space consists of a representation of the initial state, goal state, and all intervening states. For example, the problem space for solving the equation, $2X - 5 = X$, has this equation as the initial state, and $X = ___$ as the goal state. Two of the intervening states, directly after the initial state are $2X = X + 5$ and $2X - X - 5 = 0$, which were created by applying legal operators such as add 5 to both sides or subtract X from both sides. Similarly, other states are created by applying operators to these states, and so on.

Once a problem is represented as a problem space, the problem solver’s task is to search for a path from the initial state to the goal state. Means-ends analysis is a search strategy in which the problem solver works on one goal at a time; if that goal cannot be achieved directly, the problem solver sets a new goal of removing barriers, and so on. This search strategy is commonly used in computer simulations of problem solving and is consistent with the way that beginners solve problems.

Computer simulation models of human problem solving have been used to design online cognitive tutoring systems in academic disciplines (Anderson et al., 1995; Nye et al., 2014). These tutoring systems are based on a specification of the knowledge, procedures, and strategies needed to support competent problem solving.

Problem solving in realistic situations

Although classic research focused mainly on solving artificial puzzles or formal syllogisms, cognitive science research on problem solving has been shifting toward realistic situations including everyday problem solving, expert problem solving, and problem solving in subject areas (Ericsson et al., 2018; Holyoak and Morrison, 2012).

Research on everyday thinking shows that people rarely use school-taught methods to solve problems encountered outside of school (Lave, 1988; Nunes et al., 1993). For example, to determine the best buy in a supermarket—such as 90 cents for a 10-ounce can of peanuts or 45 cents for a 4-ounce can—the school-taught procedure is to compute the unit cost of each item (i.e., 9 cents vs. 11.25 cents, respectively). However, Lave (1988) found that people almost never used the school-taught procedure; instead, they invented arithmetic procedures suited to the situation, such as the ratio strategy in which the problem solver notes that the larger one is a better buy because it costs twice as much and gives you more than twice as many ounces.

Research on expert problem solving compares differences in how novices and experts solve problems in domains such as physics, medical diagnosis, computer programming, and the game of chess. For example, when Larkin (1983) asked experts and novices to think aloud as they solved physics problems, she found that experts were more likely to focus on underlying physics concepts (such as forces and weights) whereas novices focused on surface characteristics (such as pulleys and ropes). Similarly, when Chi et al. (1981) asked experts and novices to sort physics problems into groups, experts sorted problems based on their underlying physics principle (such as conservation of energy), whereas novices sorted the problems based on their surface characteristics (such as inclined planes and springs). Results of expert–novice studies suggest that experts represent and solve problems differently from novices, and so instruction can focus on helping novices think more like experts.

Another example of problem solving in realistic situations involves psychologies of subject matter, that is, research on problem solving in subject areas, such as reading, writing, mathematics, science, and history (Mayer, 2008). Instead of asking, how do people think in general, researchers ask, how do people think about testing a scientific theory, solving a mathematics word problem, or explaining why a historical event happened, or how do people think as they create an essay or make sense out of a printed passage. This approach suggests that instruction in subject matter areas should focus on helping students learn the cognitive processes and strategies required for successful problem solving.

Teaching of thinking skills

Can people improve their problem solving or thinking skills? Mayer (2008) summarized four evidence-based principles for the design: (1) Concerning what to teach, thinking is based on a collection of smaller component skills rather than improving the mind as a single intellectual ability. (2) Concerning how to teach, focus on the process of thinking through modeling rather than only on the product of thinking (i.e., getting the right answer). (3) Concerning where to teach, embed thinking skill instruction in domain specific subject areas rather than as a general all-purpose course. (4) Concerning when to teach, it is possible to teach higher order thinking skills before lower-level skills are completely automated.

One recent attempt to teach thinking skills involves computer-based games and simulations. In spite of strong claims for brain-training games, rigorous research has not provided convincing evidence to support the claims (Bainbridge and Mayer, 2018; Mayer, 2014b). However, games that are designed to teach to a specific thinking skill based on principles of skill learning have been successful (Anguera et al., 2013; Parong et al., 2017).

Reasoning and decision making form the conscious corner stone of the way that people decide what to do in difficult circumstances. There are some commonly accepted logical norms for these sorts of decisions. However, many decades of research have clearly shown that many (if not most) people do not follow these norms in any systematic way (Evans, 2008; Tversky and Kahneman, 2004). Certainly, one important question is understanding what factors determine people's tendencies to make decisions that are not normative. But, before examining these, there is another underlying question that must be addressed. The clear evidence that people show a great deal of variability in most forms of reasoning and decision-making does not preclude the possibility that there is some underlying capacity for normative, logical reasoning. In fact, there is evidence of a clear developmental progression in people's logical abilities between early childhood and adulthood (Markovits, 2017a). Thus, understanding how people arrive at conclusions and how they make decisions requires examining both aspects. In the following, I will concentrate on two major themes (1) how logical capacities develop and (2) how to characterize individual differences in reasoning and decision making.

Development of logical capacities

In the following I will concentrate on research examining developmental patterns in conditional (if-then) reasoning. This form of reasoning is critical to both logic and a variety of scientific and mathematical domains. It is accordingly the most-studied kind of reasoning and a key to understanding developmental patterns. Conditional statements take the general form "If antecedent, then consequent." Understanding conditional logic must be done by examining the four basic inferences that can be made based on assuming the truth of a single condition major premise combined with a minor premise that is the affirmation or the negation of the antecedent and consequent terms. The Modus ponens inference (which we will refer to as MP) takes the form: "If P then Q. P is true." and leads to the logically necessary conclusion that "Q is true." The Modus tollens inference (which we will refer to as MT) takes the form: "If P then Q. Q is false." and leads to the logically necessary conclusion that "P is false." The two remaining conditional inferences do not lead to a single necessary conclusion but are indeterminate, since they do not allow for a single necessary conclusion. The first of these is the Affirmation of the consequent inference (referred to as AC), which takes the form: "If P then Q. Q is true." and is compatible with either the invited conclusion that "P is true" or its negation "P is false," and thus has no single necessary conclusion. Similarly, the Denial of the antecedent inference (referred to as DA), which takes the form: "If P then Q. P is false." and is compatible with either the invited conclusion that "Q is false" or its negation "Q is true" and thus has no single necessary conclusion.

Empirical studies have given a very wide variety of results about the way that children and adolescents reason and correspondingly different interpretations of the development of reasoning. Some researchers have concluded both that logical reasoning is fairly primitive and well within the capacities of even young children (Hawkins et al., 1984; Romain et al., 1983) and others, that such reasoning is beyond the abilities of even well-educated adults (Evans et al., 2005; Oaksford and Chater, 2009). Despite what appears to be irreconcilable differences in both results and interpretation, there is a clear developmental pattern that can be discerned if one examines the way that reasoning is affected by content. In fact, one of the clearest factors that have been shown to modify reasoning is related to the specific content of the premises. The most important of these is related to what have been called "alternative antecedents." In the context of a given major premise of the form "If P then Q," an alternative antecedent is any case A, such that "If A then Q" is also true. For example, alternative antecedents for the following premise "If a rock is thrown at a window, the window will break" are the category of things that can break windows (hard objects, storms, etc.). Several studies have shown that responses to the AC and DA inferences with premises that refer to concrete and familiar content are strongly affected by the extent to which consequent terms allow spontaneous retrieval of alternative antecedents from memory (Janveau-Brennan and Markovits, 1999; Cummins et al., 1991; Cummins, 1995; Thompson, 1994). This has been measured by an alternatives generation task (Cummins et al., 1991). This simply requires asking participants to generate as many potential alternatives as possible to a given

conditional premise in a given period of time. Most studies have used a dichotomous categorization of the results of alternatives generation tasks. For example, when given a premise such as “If a rock is thrown at a window, the window will break” people will generally be able to produce a great many alternative antecedents (e.g., throwing a chair, storm, etc. are all ways that could lead to broken windows). By contrast, premises such as “If a finger is cut, it will bleed” produce relatively few alternative antecedents, since there are few alternative ways of making fingers bleed. One of the most robust empirical phenomena in conditional reasoning is the observation that when people are given major premises for which they can retrieve relatively more alternative antecedents, they will respond more frequently with the logically correct answer of uncertainty to the AC and DA inferences, while performance on these same inferences is much lower with major premises for which relatively few alternative antecedents can be produced (Cummins et al., 1991; Cummins, 1995; Markovits and Vachon, 1990). To illustrate the size of this effect, Janveau-Brennan and Markovits (1999) found that Grade 5 children (10 years of age) produced an average of 82% correct responses on the AC inference with many alternatives premises while producing only 55% correct responses on the same inference with premises for which there were relatively few alternatives. In fact, the difference between these two kinds of premises corresponds to a 1 or 2 year developmental difference. This same factor has been shown to influence reasoning in the same way among very young children (Markovits, 2000; Janveau-Brennan and Markovits, 1999), adolescents (Markovits and Vachon, 1990), and adults (Cummins et al., 1991; Cummins, 1995; Thompson, 1994).

What makes this factor important to understanding developmental patterns is that content-related differences are large enough to mask developmental effects when only the nature of inferences are examined. For example, one of the more important differences observed when only performance on specific logical forms are examined is that between the valid (MP, MT) and invalid (AC, DA) forms. Generally, performance on the latter forms of reasoning leads to lower rates of correct responding even in educated adults (Markovits, 1985; Cummins et al., 1991). If only the form of an inference were important in understanding development, then it would certainly be the case that young children should find it very difficult to respond correctly to the AC and DA forms. However, with the right content, levels of correct performance on these two logical forms can actually be greater than those typically observed with adults (Markovits and Thompson, 2008; Markovits, 2000), and greater than sometimes observed with the MP inference (which is generally accepted as the easiest of the four inferences). Thus, in order to understand how logical reasoning develops it is vital to understand the origins of the effect of content on reasoning.

Content and development

Understanding how content can influence conditional reasoning is thus a key component of the interactions between development, reasoning and content. There are different possible approaches to this problem. One such approach considers that context affects the way that conditional statements are interpreted. This acknowledges the fact that conditionals are pragmatically contextualized in a way that can alter underlying implicit inferences, and thus modify the underlying logic. There is evidence that conditional promises, of the general form: If you do X, then you will get Y are not intended as standard conditionals, but are meant to be interpreted as biconditional statements of the general form: You will get Y if and only if you do X (Markovits and Lesage, 1990; Fillenbaum, 1975; Rumain et al., 1983). In these cases, there is a strong tendency to accept the invited inference to all four inferences, even when the conditional is expressed as an if-then statement. For example, given a conditional promise such as: “If you mow the lawn, I will give you \$5,” people will conclude that if you received \$5, then you must have mowed the lawn. There is also evidence that statements expressing permissions (If you want to drink, then you must be older than 21) or obligations (If you are over 18, then you have to register for the draft) generate different forms of pragmatic structures (Cheng and Holyoak, 1985; Cheng et al., 1986; Holyoak and Cheng, 1995). However, while pragmatic factors certainly have an impact on the way that conditionals are interpreted, they do not show any developmental variability (Light et al., 1989) and cannot explain the observed variability within a given kind of conditional, when pragmatic factors are not in play.

Understanding how content affects reasoning irrespective of pragmatics requires understanding the interplay between reasoning and memory (Markovits, 2014a). One theory that makes such an explicit claim is a variant of mental model theory (Johnson-Laird, 2001, 2012; Johnson-Laird and Byrne, 1991) proposed by Markovits and Barrouillet (2002). Mental model theory supposes that when people reason with a conditional of the form If P then Q, they start by creating a very simple, initial, representation of the major premise:

P Q

Under certain circumstances, this initial model will be fleshed out by the addition of other relations corresponding to possibly true combinations of the P and Q terms. Thus, the representation corresponding to the full conditional is:

P Q

Not-P not-Q

Not-P Q

Potential conclusions are evaluated by scanning models for possible counterexamples. Thus, when evaluating the AC inference (Q is true), people with the initial model will conclude that if “Q is true” then P must be true. People with the complete model will conclude that there is no valid conclusion since “Q is true” is compatible both with P is true and not-P. Critically, the fleshing out process is essentially semantic, since it uses an abstract representation of the conditional to determine which combinations are possible. By contrast, Markovits and Barrouillet (2002) proposed that while the basic process is semantic, fleshing out is done by associative access to semantic memory, at least in the case of conditionals with concrete content.

The critical component here is the way that potential counterexamples, which in the case of the AC and DA inferences are cases of “not-P and Q” are integrated or not into the mental model used for reasoning. Available evidence clearly suggests that, for premises with familiar content, such counterexamples must be activated and incorporated from semantic memory (see [Markovits, 2014a](#) for a review of this evidence). Importantly, these must be generated online during the reasoning process. This is relatively difficult since it must be done while working memory capacity is occupied by the retention and processing of the premises. Thus, one key component that determines the relative difficulty of generating counterexamples is the relative difficulty of the search process that is required.

More specifically, there are two types of premises that require different levels of access to memory, and that determine an important developmental difference. Category-based premises are major premises that refer to a category and some properties of this category, for example: “If an animal is a dog, then it has four legs.” Counterexamples for this form of premise can be generated by searching memory for examples of other category types that share the same property (e.g., cats have four legs). The second premise type refers to causal conditionals, that is, conditionals of the form “If cause P then effect Q.” Generating counterexamples for these kinds of premises requires a more complex process, since the reasoner must be able to generate the class of causes that can lead to the effect. This kind of information is not stored directly in memory, but must be constructed on-line, which is a form of ad hoc category ([Barsalou, 1983](#)). For example, for the premise “If a rock is thrown at a window, the window will break” generating counterexamples requires generating the class of “ways to break windows,” which can give a wide variety of very different potential causes (e.g., storm, tree branch, etc.). This in turn suggests that reasoning with category-based conditionals should be less difficult than reasoning with causal conditionals, for exactly the same basic inferences ([Markovits, 2017b](#)). In addition, the distinction between category-based and causal conditionals corresponds to an important developmental period. If reasoning “logically” is defined by the ability to distinguish between the necessary MP inference and the uncertain AC and DA inferences, then even very young children 6–7-years of age can reason “logically” with category-based premises ([Markovits and Thompson, 2008](#); [Markovits, 2000](#)). However, it is not until early adolescence that children can reliably distinguish between the certain and uncertain inferences with causal conditionals ([Janveau-Brennan and Markovits, 1999](#)). Thus, the transition between the early ability to reason well with category-based premises and the ability to do so with causal conditionals determines children’s developmental trajectories during the period from initial schooling through pre-adolescence. The key factor in this period is the increasing ability of children to retain premises in working memory and the efficiency of their retrieval processes.

However, while reasoning with concrete content is certainly a major component of how people reason, another important dimension is the ability to reason with more abstract content, which mirrors the kind of reasoning found in mathematics and science. This concerns reasoning well with premises that do not have any evident real-world knowledge available in long term memory, of which the most obvious is reasoning with meaningless content, such as “If X then Y.” Such abstract forms of reasoning are very difficult, and even college students have great difficulty with these kinds of conditionals ([Venet and Markovits, 2001](#); [Markovits and Vachon, 1990](#)). One reason for this is that the counterexample generation process cannot rely on any access to memory but requires a very indeterminate form of counterexample (maybe Z can lead to Y). However, an important question is how the transition between reasoning with concrete premises to reasoning with abstract premises occurs. There is evidence that this transition is modulated by reasoning with contrary-to-fact premises, which refers to premises for which the relation in the major premise is empirically false (such as: “If a shirt is put into mud, it will become clean”). With such premises, generating a counterexample allows using memory-based information but in a complex manner, so that the kinds of counterexamples generated will correspond to an imaginary world in which mud makes things clean—leading to counterexamples of the form “dirt also makes things clean,” etc.

The ability to reason well with contrary-to-fact premises starts to be seen at the beginning of adolescence ([Markovits and Vachon, 1989](#)), well before people can reason well with fully abstract premises ([Markovits and Vachon, 1990](#)). The transitional nature of such reasoning is indicated by clear evidence that contrary-to-fact reasoning has a direct effect on abstract reasoning ([Markovits and Lortie-Forgues, 2011](#)), much more so than reasoning with familiar premises. Thus, the transition between the beginning of the ability to reason well with these kinds of premises to the ability to reason well with abstract premises represents a second developmental level, although one which is less uniformly attained than the previous one (see [Markovits, 2018](#) for a more complete synthesis).

Reasoning development as a form of divergent thinking

The model of reasoning that has been presented places great emphasis on the ability to actively generate counterexamples to given premises. During the initial period of reasoning with familiar concrete premises, this requires fairly direct access to information stored in memory. There are however clear individual differences in the way that people can access such information. One of the distinctions that is important in this context is between information which is activated directly from a given cue and information which is less directly related ([Rosen and Engle, 1996](#)). When reasoning with a given if-then premise, potential antecedents that are more directly associated with the given consequent term are more easily accessed and require relatively little cognitive effort. However, when the antecedent term is one which is highly associated to the consequent, generating alternatives becomes more difficult. For example, when people are asked to generate potential causes for the consequent “a dog scratches constantly,” they tend to produce the possibility that “the dog has fleas.” When asked to reason with the premise “If a dog has fleas, then it will scratch constantly” people tend to have greater difficulty in accepting the uncertainty of the AC inference, compared to another premise with the same consequent but with a different antecedent, such as “If a dog is ill, then it will scratch constantly” ([Quinn and](#)

Markovits, 1998). This is due to the fact that retrieving an alternative antecedent that is highly associated to the consequent requires less cognitive effort, compared to retrieving an alternative antecedent which is less highly associated. Surprisingly, this analysis is very similar to the way that divergent thinking, which is a component of creativity is conceptualized. Without going into too much detail, divergent thinking refers to the capacity to produce ideas that are conceptually distant from the prevailing context (Cropley, 2006; Guilford, 1967). For example, one of the tasks that is used to evaluate divergent thinking is the Instances task, which asks children to generate as many different and original things that can make noise as possible (Wallach and Kogan, 1965). Such tasks are very similar to the alternatives generation task that is used to categorize if-then premises as having many or few potential alternatives (Cummins et al., 1991). Individual differences in this latter task have been shown to be related to the ability to generate logical responses to causal conditionals in preadolescents (Janveau-Brennan and Markovits, 1999). In the same vein, when people are asked to rapidly produce potential causes of effects where a single cause is very strongly related to the effect (e.g., a dog scratches constantly is strongly related to having fleas), the time required to produce the second cause is also related to logical reasoning (Markovits and Quinn, 2002). These results suggest that the alternatives generation process that is assumed to underlie conditional reasoning is a form of divergent thinking, if it is assumed that the major premise generates a semantic context within which generating potential alternatives must occur. Thus, the ability to go beyond the suggested relation between the antecedent and consequent to produce other alternatives is very similar to the way that divergent thinking is conceptualized. Consistent with this idea are results which suggest that simply giving an alternatives generation task before reasoning increases the extent to which logical responses are given (Markovits and Brunet, 2012; Markovits, 2014b). More recently, studies examining very young children's ability to reason logically by accepting the MP inference and rejecting the AC inference for the same major premise have provided direct evidence for the role of divergent thinking in the early stages of conditional reasoning (de Chantal et al., 2019b; de Chantal and Markovits, 2017).

The development of logical reasoning capacities has often been conceptualized as an increase in the understanding of the basic rules of logic. The perspective that the semantic retrieval model instead suggests is that this developmental sequence is better understood as a consequence both of this understanding and of the increasing ability to generate out-of-the-box ideas that allow distinguishing necessary (e.g., MP) inferences from uncertain ones (e.g., AC). This basic role of a form of divergent thinking would also underlie the ability to reason logically with increasingly abstract content, which determines a lengthy developmental progression.

Understanding individual differences in reasoning

Overall, what the preceding model suggests is that people do develop an increasingly sophisticated ability to reason "logically." This in turn would imply that this process would reach an end-point at which everyone should be able to reason more or less logically. Unfortunately, there is a great deal of evidence that this is not the case. There are a variety of sources of the resulting variability that are generally encompassed by what are referred to as dual process models.

Dual process models

One of the problems that bedevils attempts to reason uniformly logically is the existence of several forms of heuristic factors that have a clear effect on the inferences that people actually make. One of the most studied of these is the belief-bias effect (Evans et al., 1983; Markovits and Nantel, 1989; Oakhill et al., 1989). When given inferences of the same logical form, but with putative conclusions that vary in the level of belief that people have that the conclusion is empirically true, there is a clear tendency to confound logical validity with belief in the conclusion. For example, people will tend to judge the following AC inference as valid: "All flowers have petals. Roses have petals. Therefore, roses are flowers." By contrast, they will tend to judge the inference: "All cars have motors. Airplanes have motors. Therefore, airplanes are cars" as invalid, despite the fact that both have the identical logical structure. Thus, belief in the conclusion clearly interferes with people's understanding of the logic behind these inferences (although the extent of this interference is an open question). There are other forms of what can be considered to be logical short-cuts, or heuristics, that have been documented, most extensively by the heuristics and biases program of Kahneman and Tversky (Kahneman, 2011; Tversky and Kahneman, 2004). For example, base-rate neglect leads people to misjudge the actual diagnostic value of a test. Imagine a test that can detect whether a person really has a given disease 80% of the time, and misdiagnoses 20% of cases. However, the disease is only found among 5% of the population (base-rate). People tend to think that if a person receives a positive diagnosis, the chances that they have the disease is 80%. But in actual fact, if one considers that the test will misdiagnose 20% of the 95% of people who do not have the disease, the actual probability that a positive test is associated with having the disease is much lower than 80% (it is closer to 10%). Clearly, these heuristics influence how people think. Generally, they lead to inferences that are logically inaccurate, although it has been claimed that in some cases heuristics are useful short-cuts when reasoning is complex (Gigerenzer and Selten, 2001).

A further question is how to conceptualize the interactions between heuristics and logical reasoning. Although there are some exceptions, the most common way of doing this are what are known as dual process theories (Sloman, 1996; Evans and Stanovich, 2013; Stanovich and West, 2000; Evans, 2008; Pacini and Epstein, 1999). These suppose the existence of two competing systems of reasoning which have been given a variety of names. System 1 uses rapid associatively based inferences and relies heavily on people's stored beliefs and short-cuts. This system operates at high speed and allows generating conclusions that are very rapid

and that reflect the nature of information directly stored in memory. System 2 by contrast uses more conscious forms of processing which require cognitive resources in order to generate more “analytic” conclusions, which in many cases can be “logical.” Although once again there are a variety of models, the general idea is that people’s inferences are the product of an interaction between the two systems. System 1 responses are generated very rapidly and have temporal precedence. System 2 processes must intervene before System 1 response is produced, by recognizing that System 1 response is not adequate, inhibiting this response so that it is not actually produced and generating an alternative response using more complex processes.

These models see reasoning as a sort of internal debate between two very different ways of understanding problems. There is an overall tendency to consider that the intuitive, System 1 response is often faulty, while the more analytic, System 2 response is more logical. However, this analysis is incomplete. For example, there is evidence that at least among more expert reasoners, intuitive responses can be “logical” (de Neys, 2012; de Neys and Glumicic, 2008; Thompson et al., 2018). Second, there are some good reasons for the role that intuitive, fast and heuristic reasoning plays. This kind of reasoning has the advantage of using a person’s knowledge and experience in order to generate the kinds of very rapid inferences required for active, fluid participation in a complex social and physical environment. It could in fact be argued that without these kinds of inferences people would have great difficulty in interacting, since every decision would require the kind of intensive cognitive effort that characterizes System 2 functioning. There is indeed evidence that much of human activity is underpinned by unconscious, intuitive processing (Bargh and Morsella, 2008). Thus, it is important to understand the important role that intuitive processes play, and not simply to consider them to be a form of faulty reasoning. System 2 processes require increased use of cognitive resources, and do not appear to be deployed as regularly. However, the ability to more fully understand the difference between suggested and logical judgments when the two are in conflict does mostly reside in use of System 2 processes with this basic model.

One of the problems with the dual process framework is how to understand the interaction between the two systems. Typically, these models suppose that an initial, rapid and intuitive response is produced, which must then be inhibited by the more working memory intensive form of reasoning used by System 2 processes. However, this supposes that even when the initial response is actually the one that is overtly produced, it must in many cases have been evaluated in comparison to the analytic response. This in turn implies that even when the “non-logical” response is produced, there should be some trace of the alternative. There is indeed evidence that people do have some intuition that when a System 1 response is produced, that this is not necessarily the only option (de Neys, 2012). Thus, there is some indication that people conserve the intuition of what the “logical” response is, which is consistent with results indicating some level of logical intuitions.

One of the important questions within the context of dual process theories concerns the determinants of individual differences in the relative use of the two systems. The processes required to undo an initial System 1 response require cognitive capacity, and it is generally supposed that the ability to do so is related to individual differences in cognitive capacity, such as IQ and working memory, along with other dispositional factors (Stanovich and Toplak, 2012; Stanovich and West, 1997, 2000; Toplak et al., 2011; Quayle and Ball, 2000; Pennycook et al., 2012). Thus, the chances that someone will produce the “logical” response increase as a function of measures of cognitive capacity and motivation. Of course, this assumes that slower, System 2 responses are generally more logical. This is however an assumption that has really not been tested. There is even some evidence that at least in some contexts slower reasoning can be less logical (Newman et al., 2017).

Nonetheless, the distinction between more intuitive, associative processes and more consciously analytic and working memory intensive processes seems to be well-accepted. This model has been applied to a variety of reasoning and judgment paradigms, and has been used to explain the difficulty that people have in making logical judgments. Interestingly, within a developmental context, there is some evidence that older children and adults are sometimes less “logical” than younger ones due to lesser impact of some heuristics (Artman et al., 2006; Noveck, 2001). Some of the sources of the heuristics that are used by intuitive responding come from the increasing capacity to understand the usual pragmatic forms of inference that characterize speech acts. For example, if-then premises are often intended as effective biconditionals even when they are couched in the same terms as typical if-the statements. When a parent says to a child “If you finish your meal, you’ll get dessert” the parent implicitly means that dessert will come if, and only if, the meal is finished (Fillenbaum, 1975). The tendency to interpret statements within their pragmatic context clearly is learned and appropriately increases with age, since this is necessary for social functioning. However, this illustrates one of the important paradoxes of development and reasoning. On the one hand, there is a clear increase in the ability of children to reason “logically,” that is without the constraints of assumptions due to empirical understanding. However, coupled with this is the increasing ability of children to understand the implicit underpinnings of social exchange, which increases their tendency to use these implicit rules in order to make inferences. One way of conceptualizing this developmental pattern is that the influence of System 1 intuitive inferences increases with experience, which allows people to function in increasingly fluid ways that reflect the patterns of interactions found in their individual environments. Interrupting this form of processing in order to engage System 2 processing, which is generally required to overcome intuitive responses becomes increasingly difficult and engages more of people’s cognitive resources. Thus, while there is a clear increase in reasoning ability, this is not sufficient to overcome the increasing importance of intuitive heuristics, which would account for the enduring impact of the latter on the thinking processes of even well-educated adults.

Dual strategy model

Dual process models assume that both intuitive and analytic processes co-exist in all reasoners, and that it is the interaction and potential conflicts between them that determine the extent to which a person is “logical.” However, these models also acknowledge

the presence of individual differences that might well affect how logical people are at some overall level, by modulating the ability or the motivation of the cognitive system to override an intuitive response. However, any discussion of such differences is complicated by the fact that the nature of the basic processes postulated by dual process theories remains undetermined at a very fundamental level. This is particularly the case for analytic processes which are only defined by some general characteristics (e.g., use of working memory). This is a critical problem, since the nature of analytic processes must clearly impact how this system works, and could clearly alter the general framework of dual process theories. In fact, there are at least two current and very different models of the nature of the inferential processes that all people might deploy. Mental model theories (Johnson-Laird, 2012; Johnson-Laird and Byrne, 1991) propose that when people make inferences, they first construct an internal representation of important problem parameters. This representation is used to suggest a potential conclusion and can subsequently be scanned for possible counterexamples to this conclusion. Probabilistic theories suggest that people make inferences by accessing available information about the problem context and constructing an estimation of the likelihood of a possible conclusion (Evans et al., 2007; Oaksford and Chater, 2009). Both kinds of theory present models of analytic reasoning, but although they do often make similar predictions, they suggest very different underlying processes, and are meant to represent competing models of reasoning. However, although these theories have been suggested as unique models for the way that people reason, there is some clear similarity to the analytic/intuitive dimension suggested by dual process models, with mental model theories presenting a working memory intensive process, while probabilistic theories suggest processes that are more associative and rely on rapid access to existing knowledge, something that is similar to the description of intuitive processing.

There is evidence that, as opposed to dual process accounts, these two models may represent two different modes of processing information. The recent dual strategy model of reasoning explicitly proposes that people will preferentially use one of two different strategies that roughly correspond to these two models of reasoning. This model was based on an initial proposal by Verschueren et al. (2005) as a version of dual process theory. However, Markovits et al. (2012) developed a diagnostic instrument in the context of if-then reasoning that allowed distinguishing the two different reasoning strategies. This relies on giving people access to frequency information about events related to a given inference of the form: If P then Q, Q is true. Is “P is true” a logically valid conclusion? The key version of this presents 1000 observations, of which 950 find that P is true and Q is true, and 50 find that P is false and Q is true. This suggests that if “Q is true,” the probability that “P is true” is very high, but also provides counterexamples for the same conclusion. Using this form of diagnostic allows distinguishing two forms of reasoning strategy. *Statistical* reasoners will use the probabilistic pattern to conclude that “P is true” is a valid conclusion, while *Counterexample* reasoners will use the same information to conclude that this is not a valid conclusion (although about 30% of subjects fall into an Other category, which represents people who switch strategies). Subsequent studies examined the relationship between this diagnostic and other forms of reasoning. These have found a correlation between reasoning strategy and subsequent performance on other forms of reasoning (Brisson and Markovits, 2020; Markovits et al., 2013, 2020). Although counterexample reasoners generally have been found to be more “logical” than statistical reasoners, this is not always the case (Markovits et al., 2016). More specifically, studies examining the belief-bias effect have found that strategy use is an important predictor of “logical” reasoning when there is a conflict between logic and belief (de Chantal et al., 2019a; Markovits et al., 2017). These have shown that people who are categorized as counterexample reasoners are more able to produce the valid response on these kinds of problem. This difference is even more pronounced when reasoning must be done with important time constraints (Markovits et al., 2020). Importantly, results using eye-tracking have shown that part of the difference between counterexample and statistical reasoners is attentional (de Chantal et al., 2019a). Specifically, when faced with a belief-biased inference, counterexample reasoners spend relatively more time focused on the problem premises and less on the conclusion. This along with the pattern of some previous results suggests that reasoning strategies reflect a basic difference in the way that information is processed, one that applies to more general forms of judgment. More specifically, statistical reasoners use a more intuitive form of processing in which a broader range of information is processed by accessing information which is highly associated with problem parameters. Counterexample reasoners use more focused processing related to what are considered to be important parameters of a given problem and are more sensitive to potential counterexamples to any given judgment.

This broader analysis suggests that reasoning strategy should be a determinant of individual differences in a much broader range of judgments than are involved in the inferential tasks that led to its development. Corresponding to this, reasoning strategies have been found to modulate well-known gender differences in both the processing of negative emotions (Markovits et al., 2018) and mental rotation judgments (Markovits, 2019), with gender differences accentuated among statistical reasoners and attenuated among counterexample reasoners. More recently, reasoning strategy has been found to predict the extent to which people are prone to a variety of social stereotypes (Gagnon-St-Pierre et al., 2020).

In addition to these, recent studies have examined the extent to which reasoning strategies can predict the interaction between heuristic and logical responding compared to the most common explanatory mechanisms derived from dual process theories (i.e., working memory). Thompson and Markovits (2021) found that reasoning strategy alone explained variation in the extent to which logical reasoning is used in an array of heuristic judgments over and above the contribution of working memory, and other factors. In fact, studies which have introduced time constraints on reasoning have found that the relative contribution of reasoning strategy increases when time is reduced (Markovits, 2019; Markovits et al., 2020).

Overall, these studies suggest that there is a clear individual difference in the way that people process information that is critical to any form of reasoning. Statistical reasoners tend to use a more intuitive, probabilistic form of processing and are accordingly more influenced by heuristics and belief. Counterexample reasoners use a more focused form of representation of key problem parameters, and are correspondingly less influenced by heuristics and belief. Although most studies examining this model have

looked at adults, there is some evidence that this same distinction might apply to children (Markovits et al., 2019). This in turn suggests that at least some of the variation in learning and understanding basic concepts is related to the way that children are processing information in different ways.

Conclusion

Both the developmental patterns found with conditional reasoning and the individual differences highlighted by the dual strategy model suggest that reasoning and decision making cannot be understood as the result of applying abstract rules. They are better understood as forms of problem solving which are defined by a variety of different kinds of information. Whereas some of this information is explicitly described, other kinds of information will be accessed during the reasoning process. This latter reflects active use of people's store of knowledge and beliefs. In some cases, such as the production of potential alternative antecedents when reasoning with conditionals, this information is critical to producing the "logical" response. In other cases, such as evaluating the believability of a given conclusion, accessed information can result in producing the "nonlogical" response. One of the key components of reasoning ability is understanding the way that information that is actively accessed by a reasoner can have multiple effects. The fact that even well-educated adults, who are able to reason with abstract content at a reasonably high level, are still prone to the various heuristic effects shows the difficulty of differentiating these effects. One of the goals of education must therefore be the development of understanding of the way that people use implicitly generated information and how to distinguish contexts in which this information is useful from those in which it is harmful.

Self-concept is a person's perceptions of themselves, formed through their experiences with and interpretations of their environment, and impacted by others' evaluations of them (Shavelson et al., 1976). It includes feelings of self-confidence, self-worth, self-acceptance, and perceptions of one's competence and ability. It affects how we act, feel, and adjust to a changing environment. Indeed, past research has shown positive self-concepts to be important for a variety of outcomes such as social and emotional health (Harter, 2012; Marsh et al., 2004), academic functioning (Chen et al., 2013; Marsh and Craven, 2006; Marsh and Yeung, 1997a), social and personal adjustment of children and adolescents (Harter, 1990; Parker et al., 2020), approaches to learning (Burnett et al., 2003), emotional adjustment and socialization (Donahue et al., 1993), bullying (Marsh et al., 2004), elite athlete success (Marsh and Perry, 2005), and parent-adolescent relations (Barber et al., 2003). Therefore, the enhancement of self-concept is a major goal in many fields such as education, child development, and sports.

In this chapter, we focus on self-concept within the field of education and the construct of academic self-concept (ASC). ASC is an individual's perceptions of their academic performance, and it sits within the multidimensional and hierarchical structure of self-concept. We first provide an overview of self-concept and its structure, to allow for a fuller conceptualization of ASC. We then discuss research on the link between ASC and educational outcomes.

The structure of self-concept

Self-concept is multifaceted and hierarchically organized, with global, general self-concept (also known as self-esteem) at the apex, inferences about the self in broad domains (e.g., social, physical, and academic) in the middle of the hierarchy, and perceptions of personal behavior in specific situations at the base of the hierarchy (Shavelson et al., 1976). Although contested in the 60s and 70s by proponents of a unidimensional structure of self-concept (Coopersmith, 1965; Marx and Winne, 1978), this multidimensional structure of self-concept was thoroughly assessed and confirmed via the Self-Description Questionnaire (SDQ; Marsh et al., 1983) by Marsh and Shavelson (1985).

Marsh and Shavelson (1985) conducted a series of studies with preadolescent and older adolescent children. They demonstrated that self-concept grew more and more multifaceted as children aged. While the self-concepts of preadolescent children comprised seven dimensions (i.e., physical appearance, physical abilities, peer relationships, parent relationships, reading, mathematics, and other school subjects), the self-concepts of older adolescent children was best explained by 13 dimensions (general, same-sex, opposite sex, parent relationship, emotional stability, problem-solving, religion/spirituality, honesty/dependability, physical ability, physical appearance, reading, math, and other school subjects). Providing evidence for the robustness of these factors, Marsh and Shavelson (1985) found that the correlations between specific self-concepts were small and that these correlations decreased with age. In the preadolescent samples, the average correlation between factors declined from $r = 0.27$ in Grade 2 to $r = 0.14$ in Grade 4, and in the older adolescent samples, all r s were lower than 0.10. Further support for this trend was provided by Marsh et al. (2005), with the development of a version of the SDQ for preschool children. Although children as young as four were able to distinguish between multiple dimensions of self-concept, the correlations between the facets were much higher at this young age ($r = 0.73$) compared to the typically small correlations observed with older children and adolescents.

Impact of multidimensional structure on self-concept research

Before we proceed to discussing the link between ASC and learning and other educational constructs, it is important to note how the multidimensionality of self-concept impacts research using global versus domain-specific measures. Although global self-concept

(also referred to as self-esteem) measures have stronger associations with global outcomes than domain-specific outcomes, the opposite is true for domain-specific self-concept measures. Therefore, using self-esteem measures in studies with a focus on broad, global outcomes is appropriate. However, ASC is more relevant to academic outcomes, and specific components of ASC are more relevant to outcomes concerning specific school subjects. For instance, [Valentine et al. \(2004\)](#) showed that stronger effects of self-belief measures are found when assessing self-beliefs specific to the academic domain and when self-beliefs and achievement are matched by the domain (i.e., same subject area).

The link between academic self-concept and educational outcomes

Past studies have consistently shown ASC to positively impact a host of learning and other educational outcomes, such as academic achievement ([Marsh and Craven, 2006](#)), interest and satisfaction in school ([Marsh et al., 2005](#)), course selection ([Marsh et al., 2019](#); [Marsh and Yeung, 1997a](#); [Parker et al., 2014](#)) persistence, and long-term attainment ([Guo et al., 2015a,b](#); [Marsh and O'Mara, 2008](#)). These effects hold even after accounting for prior achievement and IQ, suggesting that a positive ASC is highly desirable not only as a goal, but also to facilitate subsequent learning and academic accomplishments. In this section, we first outline the literature with regard to ASC and academic achievement, and then highlight how ASC is beneficial for other learning outcomes.

Academic self-concept and academic achievement

Correlational evidence

Studies have shown that ASC is substantially correlated to numerous academic achievement measures (e.g., test scores, school grades), and across domains. Evidence for the association between ASC and test scores has been garnered from numerous cross-national databases. For instance, using data from 15-year-old students from the 26 countries participating in the Programme for International Students Assessment (PISA) 2000 cohort, [Marsh and Hau \(2003\)](#) showed that the overall effect (in terms of standardized beta coefficients—for this and for the following estimates) of individual student academic achievement (non-subject specific) on individual student ASC was 0.38. [Seaton et al. \(2009\)](#); 41 countries in PISA 2003) and [Marsh et al. \(2020\)](#); 68 countries in PISA 2012) showed that the overall effects of math achievement on math self-concept were 0.52 and 0.91, respectively. [Nagengast and Marsh \(2011\)](#); 56 countries in PISA 2006) showed that the overall effect of science achievement on science self-concept was 0.17. Lastly, [Basarkod et al. \(2020\)](#); 72 countries in PISA 2018) showed that the overall effect of individual student reading achievement on individual student reading self-concept of competence was 0.35 and on individual student reading self-concept of difficulty was -0.32 . Note that all these effects were from three-level models (students nested within schools nested within countries) that accounted for a host of independent (e.g., school- and country-average achievement) and control variables (e.g., gender, socio-economic status).

Using another international dataset—the combined Trends in Mathematics and Science Study (TIMSS) and Progress in International Reading Literacy Study (PIRLS) dataset from 2011—[Guo et al. \(2018\)](#) also showed cross-national evidence for the robust association between ASC and achievement for 4th grade students (from the 15 Organization for Economic Cooperation and Development [OECD] countries that participated in these surveys). Specifically, they showed that the overall zero-order correlations between self-concept and individual student achievement in the same domain were 0.31 for math, 0.20 for science, and 0.40 for reading. The average beta estimates from two-level models in each country (controlling for other independent variables and covariates) were 0.42 for math, 0.19 for science, and 0.42 for reading.

Importantly, correlational studies have also shown that the link between ASC and achievement is stronger than that for other learning measures with achievement ([Marsh and Martin, 2011](#)). This is best highlighted by results of the OECD-PISA's Students' Approaches to Learning instrument (SAL; [Marsh et al., 2006](#)). The SAL measures 14 factors that assess self-regulated learning strategies, self-beliefs, motivation, and learning preferences. Marsh et al. evaluated SAL responses from nationally representative samples of approximately 4000 15-year-olds from each of 25 countries ($N = 107,899$). Across this set of 14 factors, mathematics and verbal achievement were consistently more strongly correlated with the three (math, verbal, and academic) self-concept measures than they were with any other SAL constructs. Furthermore, formal tests of factorial invariance showed that the pattern, direction, and relative sizes of these correlations were relatively invariant across the 26 countries.

Longitudinal evidence

Evidence from cross-national datasets attest to the robustness of the association between self-concept and achievement measures. However, these datasets have been cross-sectional, and therefore, do not provide clarity on the causal relationship between the two constructs. For this, we need to turn to longitudinal studies. [Byrne \(1984\)](#) proposed three criteria that studies addressing causal relationships must satisfy: (a) a statistical relationship must be established, (b) a clearly established time precedence must be evident, and (c) a causal model must be correctly specified.

Early studies addressed the question of what comes first, achievement or self-concept, and tested two competing hypotheses: the self-enhancement model and the skill-development model. According to the self-enhancement model, self-concept is a primary determinant of academic achievement. That is, individuals who have high academic achievement levels do so because of their high levels of ASC. In contrast, the skill-development model posits the opposite causal ordering; ASC emerges principally as a consequence of academic achievement so that it is enhanced by developing stronger academic skills. These early studies (e.g., [Calsyn and](#)

Kenny, 1977), however, aimed to determine which of these paths was the predominant one, rather than whether paths in both directions were significant. That is, self-concept research did not claim that it was solely self-concept that caused achievement, or vice versa, but that both these constructs played some role in predicting the other. Much like the nature versus nurture debate that has plagued psychology, the question was not *which* of these two contrasting hypotheses was “true,” rather *whether* both of these acted in conjunction. In addition, these early studies were not methodologically strong as they were largely based on correlational evidence and did not use more methodologically appropriate techniques such as SEMs (see Marsh, 1990 for a detailed review of these arguments).

It was not until the 1990s that both the self-enhancement and skill-development models were tested simultaneously in the reciprocal effects model (REM). This was first done by Marsh (1990) with data from the large, nationally representative US Youth in Transition study. He considered data from Times 1 (early 10th Grade), 2 (late 11th Grade), 3 (late 12th Grade), and 4 (1 year after normal high school graduation). Three latent constructs were considered: academic ability inferred on the basis of four standardized test scores, ASC inferred from self-report responses, and school grades. Of particular importance were the effects of latent constructs in one wave on latent constructs in subsequent waves. At T2, ASC was influenced by academic ability and T1 ASC, but not by T1 grades. At T2, school grades were influenced both by T1 ASC and by T1 school grades. Similarly, school grades at T3 were influenced significantly both by T2 ASC and by T2 grades. ASC at T4 was influenced significantly by ASC at T2 (there was no T3 ASC measure), but not by T3 school grades. The findings provide strong support for the effect of prior self-concept on subsequent school grades as they spanned the two time intervals.

Since the Marsh (1990) seminal study, there have been plenty of empirical studies, cross-cultural studies, as well as meta-analyses that lend support to the REM predictions (Huang, 2011; Marsh and Martin, 2011; Marsh et al., 2018; Valentine et al., 2004). Marsh et al. (2018) demonstrated the reciprocal effects of math self-concept and math achievement over 6 years in a sample of 3370 German students from 42 secondary schools. They used two measures of math achievement—test scores and grades. For models run separately for each of the achievement measures, and with time-invariant cross-lags, the path estimates (standardized beta weights) from prior math self-concept to subsequent math test scores was 0.05 ($SE = 0.01$) and to subsequent school grades was 0.10 ($SE = 0.01$). The path from prior test scores to subsequent math self-concept was 0.13 ($SE = 0.02$) and from prior school grades to subsequent math self-concept was 0.16 ($SE = 0.01$). Thus, although the estimates for achievement predicting self-concept were larger, both directions were significant and positive (results from a model simultaneously accounting for both school grades and test scores were similar and significant, albeit marginally smaller).

Generalizability of evidence

Across cultures

The REM of ASC and achievement has been shown in different cultural settings, such as in a large nationally representative sample of Hong Kong students (Marsh et al., 2002) and large samples of East and West German students at the time of the fall of the Berlin Wall (Marsh and Köller, 2003; Marsh et al., 2001). Support for the generalizability also comes from research based on French-speaking Canadian primary students (Guay et al., 2003), German high school students (Marsh et al., 2005), and 487 high school students (Grades 7, 8, and 9) from mainland China (Yeung and Lee, 1999).

More generally, in their meta-analysis of REM studies, Valentine et al. (2004) considered the country where the sample was drawn from as a moderator variable. However, they found that support for the REM did not differ as a function of country. Although this research provides cross-national and cross-cultural support for the REM, we note that the majority of the research comes from Western and industrialized countries, so it is premature to claim that support for the REM is universal.

Across achievement tracks

Seaton et al. (2015) tested the equivalence of the REM across a sample of high school students who attended academically selective ($n = 738$) and mixed-ability comprehensive ($n = 2048$) schools in Australia. The average path estimate (standardized beta weight) for prior mathematics self-concept predicting subsequent mathematics achievement was 0.06, and that for prior mathematics achievement predicting subsequent mathematics self-concept was 0.07. All cross-paths were significant. Further, their multigroup analyses revealed that these reciprocal effects were present for students attending both academically selective and mixed-ability comprehensive schools. In addition, there were no differences between the groups in either the size or the direction of the paths.

Similarly, Arens et al. (2017) examined the REM in a sample of German students ($N = 3425$) from grades 5 through 9, who attended different achievement tracks. The average path estimates (standardized beta weights) across all groups and time points were as follows: math self-concept to math test scores, 0.056 (range = 0.054–0.059); math self-concept to math school grades, 0.047 (range = 0.045–0.049); math test scores to math self-concept, 0.082 (range = 0.075–0.093); and math school grades to math self-concept, 0.087 (range = 0.083–0.093). Thus, the paths were consistent across time intervals, types of achievement measures, and different achievement tracks. Although the results presented here were from a combined model, they were also replicated when separate models were used. In addition, as the students were tracked from when they were in Grade 4 to Grade 9, this study also provided evidence for the REM to be robust across age.

Across age groups

A study by Guay et al. (2003) also addressed the issue of whether the REM held across age groups. They used a multicohort, multi-occasion design, a methodological approach that is especially well-suited to address this issue. In particular, they considered responses of students at T1 in Grades 2–4 (i.e., three age cohorts 8–10 years of age). Responses for all three cohorts were then

collected annually for the next 3 years (i.e., the three measurement occasions). They found strong support for the REM for all three age cohorts, and these results were reasonably invariant when rigorously tested with multigroup tests of invariance across the three age cohort groups.

Across subject areas

Although most studies examining the REM have focused on math, research in the domains of reading and science has also provided evidence for the model (e.g., Chiu, 2012; Sewasew and Koester, 2019). For instance, Sewasew and Koester (2019) analyzed the REM for reading using a sample of primary school children in the United States from the Early Childhood Longitudinal Study-Kindergarten (ECLS-K) dataset. The paths from prior reading self-concept to subsequent reading achievement ($\beta = 0.08$), and from prior reading achievement to subsequent reading self-concept ($\beta = 0.25$), were both significantly positive. Indeed, as is the case with research in the math domain (e.g., Marsh, 1990), they also found that the path from achievement to self-concept was stronger than the path in the opposite direction. Evidence for the REM for reading has been observed in multiple languages such as English, German, and Chinese (Chen et al., 2013; Möller et al., 2014; Niepel et al., 2014).

Controlling for other variables

The bidirectional causal relationship between self-concept and achievement holds even after controlling for other related constructs. For instance, Seaton et al. (2014) used a sample of 2786 Australian high school students (ages 11–17) who participated at four time points, each 6 months apart. Separate models indicated that there were reciprocal associations between mathematics self-concept and achievement, as well as between mathematics performance goal orientation and achievement. There was little evidence of such reciprocal relations between mastery goal orientation and achievement. Important to our discussion here, only self-concept had significant reciprocal relationships with achievement when all variables were included in a single model. Similarly, using a sample of 702 8th grade students in China, Xu (2018) showed that the positive effect of math homework self-concept on math achievement remained even after controlling for students' levels of interest and effort for the homework.

Meta-analytic evidence for moderators

In a theoretical review and meta-analysis of studies on the REM between self-beliefs (including self-concept, self-efficacy, self-esteem), Valentine et al. (2004) reviewed 55 publications on the REM. This meta-analysis included 60 independent samples and 282 different effect sizes. The effect of prior self-beliefs on subsequent achievement, controlling for the effects of prior achievement, was highly significant overall and positive in 90% of the studies in their meta-analysis (average $\beta = 0.08$, 95% CI = 0.06–0.10). The same was true for achievement predicting self-beliefs (average $\beta = 0.15$, 95% CI = 0.12–0.18).

Valentine et al. (2004) considered a wide variety of potential moderators of the REM effects: year the study was published/reported; base year of data collection; sample size of the study; stability of the achievement measure (i.e., T1–T2 stability coefficient); reliability of the self-measure; the number of variables used as controls in the analysis; whether the effect size was from an analysis of manifest or latent variables; use of a convenience sample versus random selection from a known population; age of students; type of achievement; time interval between the collection of T1 and T2 measures; and country from which the sample of students came. However, none of these potential moderators had a significant effect on the size of the REM. These meta-analysis results provide compelling support for the robustness and generalizability of the REM in a way that could not be achieved on the basis of any single primary study.

The only two variables that had a substantial moderating effect on the REM was the globality (versus specificity) of the self-belief measure and school transition. In support of a multidimensional perspective of self-concept (and indeed, self-belief measures in general), Valentine et al. (2004) found that the effects of prior self-beliefs were significantly stronger when the self-belief measure was based on academic self-beliefs rather than on global measures such as self-esteem. This was also the case when the self-belief and achievement measures were matched in terms of subject area (e.g., mathematics achievement and math self-concept). In particular, they reported little evidence of any effects of global or generalized self-beliefs (e.g., self-esteem) on academic achievement. In terms of school transition, they found that the strength of the REM was weaker in studies where students experienced school transition (e.g., from elementary school to middle school). In particular, the effects of prior self-beliefs (collected prior to the transition between school stages) on subsequent achievement (collected after the transition) were smaller than in studies where there was no transition.

A comprehensive meta-analysis on the reciprocal relationship between self-concept (rather than all self-beliefs) and achievement by Huang (2011) examined 39 independent and longitudinal samples by integrating meta-analytic and path analysis procedures. Huang (2011) found similar results to Valentine et al. (2004). Specifically, the mean observed correlation between prior self-concept and subsequent achievement ranged from 0.20 to 0.27, whereas that for the opposite path ranged from 0.19 to 0.25. The only significant moderator of the REM was the globality (versus specificity) of the self-concept measures used. The other moderators they tested (i.e., globality of academic achievement measure, the indicator of academic achievement, delay between time waves, mean age of sample at baseline) were not significant.

These meta-analyses provide clear support for the REM, the robustness and generalizability of the effects, the theoretical focus on a multidimensional perspective, and the methodological focus on a construct validity approach that has been central to REM studies and self-concept research more generally.

Other learning outcomes

Besides being a positive and significant predictor of academic achievement, ASC is also important for a host of other learning and educational outcomes. For instance, Marsh and Yeung (1997a,b) found that, whereas self-concept, academic achievement, and coursework selection were all highly correlated, prior self-concept was a much better predictor of subsequent coursework choice than was prior academic achievement. Indeed, self-concept predicted course selection in many different academic subjects (i.e., English, math, science, computer science, history, economics, geography, foreign language, and industrial arts). In another study, Marsh et al. (2005) tested the REM between self-concept and achievement (both school grades and test scores) and included academic interest in the model. They conducted these SEMs using longitudinal data based on two large, nationally representative samples of German high school students. For both samples, they found clear support for the REM based on ASC and achievement, demonstrating that the effect of prior math self-concept was substantial for subsequent math school performance as well as for math test scores. Important for our discussion here, prior self-concept also significantly influenced subsequent academic interest measures beyond the effects of earlier measures of school performance, achievement test scores, and academic interest. In contrast, prior academic interest had only a small effect on subsequent self-concept and little or no effect on either school performance or test scores beyond what could be explained by self-concept.

Self-concept is also a positive predictor of academic aspirations and attitudes toward school. For example, Marsh (1991) investigated the effect of school-average ability on a wide range of educational outcomes including academic aspirations. When controlling for ASC, the previously confirmed negative effects of school-average ability were reduced and, as such, ASC showed considerable total and direct effects on academic aspirations. In a study by Green et al. (2012), self-concept was shown to positively predict attitudes toward school ($\beta = 0.22$ and 0.28) over and above the effect of academic motivation constructs. In turn, attitudes toward school positively predicted class participation, homework completion, test performance, and negatively predicted absenteeism.

Wouters et al. (2011) demonstrated that self-concept also predicts ($\beta = 0.28$) academic adjustment (i.e., the extent to which students can meet their academic demands) and success in the 1st year of higher education ($\beta = 0.20$), after accounting for high school academic achievement. They conducted this study with a sample of 536 students in Belgium, a country where more than half of the students who enroll in university do not graduate (Groenez et al., 2003). Indeed, the OECD has reported that the average university completion rate across 24 OECD countries is 36%. Thus, the finding that self-concept positively predicts meeting university demands and success at university, in the crucial adjustment period of 1st year, is an important one.

Summary and implications

This chapter emphasizes the importance of ASC for learning and other educational outcomes. We provide clear and robust evidence regarding the bidirectional and reciprocal relationship between ASC and achievement. This causal ordering is consistent across cultures, achievement tracks, ages, and subject areas. It also holds when controlling for other important educational constructs, and is only moderated by the globality versus specificity of the measures used, and the presence versus absence of school transition. In addition, we also outline studies that show ASC positively predicts other learning outcomes such as coursework selection, academic interest, academic aspirations, attitudes toward school, academic adjustment, and success in higher education, while controlling for prior achievement. Although the sheer number of studies that show the REM is promising, it should be noted that the majority of the studies utilize the same methodology (i.e., cross-lag panel models; CLPM). Future research is required to supplement these studies by testing the causal relationship between self-concept and achievement with newly developed longitudinal methods such as the random-intercept cross lag panel model (RI-CLPM) or the bivariate STARTS (Stable Trait, Autoregressive Trait, and State) model (see Usami et al., 2019 for a description of these methods).

It is important to note, however, that the cross-lag estimates from these models would need to be interpreted differently (Orth et al., 2020). For instance, a significant positive cross-lag from self-concept to achievement using the CLPM would indicate that individuals who have higher self-concept at Time 1 are more likely to have higher achievement levels at Time 2, compared to individuals who have lower self-concept at Time 1. In contrast, the same cross-lag in a RI-CLPM would imply that individuals who have higher self-concept than usual at Time 1 will show subsequent increases in achievement, while individuals who have lower self-concept than usual at Time 1 will show subsequent decreases in achievement.

The fact that self-concept and achievement are mutually reinforcing has important implications for policy and practice. On the one hand, the finding that self-concept promotes achievement implies that programs and teaching practices should be designed to protect self-concept (self-enhancement interventions). On the other hand, the finding that achievement promotes self-concept provides a basis for increasing standards and accountability for student learning (e.g., mandatory promotion/graduation requirements; skill development interventions). Based on their meta-analytic findings, however, Huang (2011) concluded that “as high self-concept is related to high academic performance and vice versa, intervention programs that combine self-enhancement and skill development should be integrated” (p. 505). Thus, the ideal interventions would not aim to improve self-concept or achievement solely, but both concurrently.

It is important to note that although there is ample evidence for positive and significant paths in both directions, the path from achievement to self-concept is generally stronger than the path from self-concept to achievement. Still, one cannot be improved at the detriment of the other. For example, if teachers enhance students' ASCs without improving achievement, then self-concept gains

are likely to be short-lived. However, if teachers improve students' academic achievement without also fostering students' self-beliefs in their academic capabilities, then the achievement gains are also unlikely to be long lasting. If teachers focus on either one of these constructs to the exclusion of the other, both are likely to suffer. In addition, as evidenced by the studies discussed in this chapter, especially through the moderators examined in the reported meta-analyses, the REM effects tend to be stronger in specific domains, rather than in academia in general. It follows then that interventions that aim at increasing achievement may want to focus on specific domains rather than achievement in general. In this way, intervening to increase achievement and self-concept within the same domain may multiply the benefits.

Introduction

In the social cognitive theory of human functioning, [Bandura \(1989, 1997\)](#) posits the reciprocal interactions among person, behavior, and environment. This theory emphasizes human agency, considering humans as active agents who pursue a goal and exercise control over the course of actions toward the goal. Humans can interpret their behaviors and environment, reflect upon themselves, and regulate their behaviors based on expectations, which in turn can influence their environment. Self-efficacy, the personal conviction that one can perform a given task successfully, lies at the center of this whole self-regulatory process. Without strong self-efficacy, individuals are not able to feel a sense of agency in a situation and are less willing to engage in a task even for potentially positive outcomes. In academic contexts, self-efficacy (i.e., academic self-efficacy; [Schunk, 1991](#)) plays an important role in affecting a vast array of learners' academic motivation and behaviors, including their goal pursuits, academic emotions, choice, engagement, self-regulation, and achievement.

Definition of self-efficacy

Self-efficacy represents one's personal conviction about her or his capability to successfully perform a specific behavior or a specific task at the desired level ([Bandura, 1997](#); [Schunk, 1991](#)). It is a subjective judgment and, as such, does not necessarily reflect one's actual capabilities. Rather, individuals collect relevant information from diverse sources about themselves, the task, and surrounding environments and estimate the possibility that they could successfully accomplish the task under the given circumstances. Self-efficacy perceptions are thus highly context-specific. For example, students may hold different self-efficacy beliefs for performing well depending on the specific problem, subject (e.g., algebra, biology, history), domain (e.g., verbal, quantitative), test format (e.g., multiple-choice, short answer, essay), and testing environment (e.g., timed, open-book, online, take-home).

Self-efficacy should be distinguished from outcome expectancy, which is one's expectations about the response-outcome contingency ([Bandura, 1997](#)). Whereas self-efficacy represents the conviction about one's own capabilities to execute a certain behavior, outcome expectancy represents the belief that particular behaviors will lead to a certain outcome. Both self-efficacy and outcome expectancy are required to initiate and maintain behaviors. However, even with a high outcome expectancy, people who do not believe in their own effectiveness are not likely to initiate the task or actively cope with challenges ([Bandura, 1977](#)). Self-efficacy lies at the core of human agency because it enables people to engage in the course of actions to achieve desired outcomes.

Another similar yet separable concept from self-efficacy is perceived control ([Bandura, 1997](#); [Schunk, 1991](#)). Closely related to outcome expectancy, perceived control is a causal belief regarding the pursued outcome rather than the behavior itself. Whereas self-efficacy is a belief in whether one can execute the requisite behavior, perceived control is a belief in whether one can exert control over an outcome and is therefore similar to the perceived locus of control ([Rotter, 1966](#)). Students may have strong self-efficacy for getting a good score on the upcoming test but have low perceived control over the actual grade because of the normative evaluation system. The perceived uncontrollability of the desired outcome can cause learned helplessness ([Miller and Seligman, 1975](#)). Regardless of the level of self-efficacy, people may feel helpless when they see the outcome to be independent of their own behaviors.

Self-efficacy is also different from other evaluations about self, such as self-esteem or self-concept ([Bong and Clark, 1999](#); [Bong and Skaalvik, 2003](#)). Self-esteem is an evaluation of oneself in general, while self-concept is a conception of oneself in a specific domain. Both self-esteem (e.g., "I feel proud of myself") and self-concept (e.g., "I'm good at math") are relatively stable and include emotional as well as cognitive reactions to the self and its attributes. In comparison, self-efficacy is more malleable and largely

cognitive, since it is a judgment of one's capability to perform a specific task at a designated level (e.g., "I'm highly certain that I can learn to use computers"; Bandura, 2006). Emotional reactions are considered as correlates and consequences of efficacy judgments rather than components of self-efficacy.

Although both self-concept and self-efficacy tap competence perceptions, they can be further distinguished. Self-concept is an aggregated evaluation of one's competence in a given domain, which depends heavily on past achievements and intra- and inter-individual comparisons (Bong and Skaalvik, 2003; Möller et al., 2009; Zimmerman, 2000). Compared to self-efficacy, self-concept is relatively past-oriented and normative. In contrast, self-efficacy is a situation-specific expectation of successful performance on a given task and, as such, more future-oriented than self-concept. While self-efficacy judgments also rely heavily on one's past performances and use social comparative information, the most critical question is whether individuals feel confident that they can accomplish what they set out to achieve. In this sense, self-efficacy should be viewed as a goal-referenced construct than a normative construct (Bong and Skaalvik, 2003).

Sources of self-efficacy

Self-efficacy is shaped through information coming from diverse sources. Four major sources that have been established to influence self-efficacy formation are mastery experience, vicarious experience, social persuasion, and physiological and affective states (Bandura, 1997; Usher and Pajares, 2008).

The first and the most influential source that individuals turn to when gauging their self-efficacy is mastery experience—one's past experiences of successes and failures (Bandura, 1997; Byars-Winston et al., 2017). Mastery experience consists of one's previous encounters with the same or similar tasks and provides individuals with authentic and the most reliable information for estimating their confidence. When individuals' attempts end up with success or failure, their self-efficacy toward the same or similar tasks moves upward or downward, respectively. The experience of overcoming challenges and eventually succeeding on a difficult task is powerful evidence of one's competence and noticeably boosts one's self-efficacy. Yet, it should be noted that it is individuals' own interpretations and attributions of these success and failure experiences that wield influence on subsequent self-efficacy. The same success or failure can bring about varying degrees of changes in self-efficacy beliefs across individuals, depending on their perceptions of contexts and conditions that may moderate the influence of mastery experience on efficacy appraisals (Bandura, 1997). For example, even when a student receives an A on a writing assignment, her self-efficacy for writing may not improve much if she thinks that is because the assignment was quite easy (i.e., task difficulty) or benefitted from the help from a writing advisor (i.e., external aid).

Vicarious experience serves as the second source of self-efficacy information (Bandura, 1997; Usher and Pajares, 2008). Individuals can gauge the likelihood of their success by consulting their own past performances as well as their observations of others' performance on the same task. This source is useful especially when direct experience is not available or there is no absolute barometer of competence (Bandura, 1997). For instance, even with no prior experience, observing others' success and failure on a given task could lead individuals to expect a similar level of performance when they try it themselves. The performance of others can also serve as a standard against which one's own performance is socially compared. Individuals' self-efficacy will be enhanced if they performed better than others did but diminished if they performed worse than others did. Perceived similarity of the model to oneself increases the personal relevance of the information conveyed by the model and increases the power of this self-efficacy source (Schunk, 1987). Performances of peers who share similar backgrounds and characteristics with oneself can be more informative than those of peers who do not. In a related vein, between the coping model who displays gradual improvement in performance and the mastery model who demonstrates proficient performance from the start, the coping model is generally more helpful to struggling students because of the similarity the students perceive in the model (Schunk et al., 1987; Schunk, 1987).

The third source of self-efficacy is social persuasion by significant others (Bandura, 1997; Usher and Pajares, 2008). For example, verbal and nonverbal messages from family members, teachers, and peers, which can be either supportive or destructive, convey information to learners regarding the possibility of their success in a certain domain or task (Ahn et al., 2017). Although its influence may be weaker and short-lived compared to that of direct mastery and indirect vicarious experiences, persuasions could provide an effective means to strengthen one's self-efficacy when combined with multifaceted strategies to develop actual skills (Bandura, 1997). Self-efficacy information from this source is weighted differently depending on both the perceived credibility of persuaders and the contents of persuasion. Social persuasion by individuals who are judged to be trustworthy, knowledgeable, and competent enough to deliver accurate diagnostic information about one's ability is more powerful in shaping the listener's self-efficacy than social persuasion by individuals who lack these qualities (Won et al., 2017). Social persuasion also becomes more reliable when the contents of persuasion are plausible to the listener when considering the temporal proximity of upcoming performance and the nature of a task (Bandura, 1997).

Physiological and affective states are the fourth and the least influential source of self-efficacy information (Bandura, 1997; Usher and Pajares, 2008). Individuals can sense their physical reactions (e.g., fatigue, pains) and unpleasant emotional symptoms (e.g., negative mood states, arousal, and stress reactions toward a task) and interpret them as signs of their vulnerability and lack of competence (Bandura, 1997). However, information from this source is quite ambiguous to interpret accurately and thus often biased due to various personal and environmental factors such as one's past experiences, pre-existing self-efficacy beliefs, and situational cues that affect attributions. For instance, rapid heartbeats before embarking on a task can be interpreted as excitement by

successful and confident learners but anxiety by less successful and insecure learners. Likewise, if learners engage in a task right after running, the same rapid heartbeats would be attributed to running rather than anxiety and hence may not influence beliefs of self-efficacy.

Roles of age, gender, and culture in self-efficacy formation

Research shows that the age, gender, and culture of individuals can affect their self-efficacy development (DiBenedetto and Schunk, 2018; Schunk and DiBenedetto, 2020; Schunk and Meece, 2006; Usher and Weidner, 2018). Self-efficacy tends to decrease and become more accurate as students get older (Schunk and Meece, 2006). Whereas young children are often overly confident about their ability, older students who are equipped with superior metacognitive capability form more realistic assessments of their ability by integrating self-efficacy information from diverse sources (Muenks et al., 2018). Older students are also more sensitive to social comparative information and start to have differentiated conceptions of ability (Muenks and Miele, 2017; Nicholls, 1978, 1984). To young children, those who spend greater effort are also the ones with superior ability. To older children, having to spend greater effort than others to achieve the same level of success is evidence of a lack of ability. These developmental differences suggest the importance of using age-appropriate goals and evaluation strategies for enhancing self-efficacy. While providing metacognitive guides to show progress and task mastery would be effective for young children, more deliberate approaches using norm-referenced evaluations and effort attributions may be necessary for older adolescents (cf. Amemiya and Wang, 2018). Recent evidence suggests that mastery experiences are particularly crucial in the self-efficacy formation of pre-college students (elementary, middle, high school) than that of college samples (Byars-Winston et al., 2017).

Self-efficacy development differs by gender as well. Gender differences have been identified in the mean-level of self-efficacy beliefs in several gender-typed domains such as math (Else-Quest et al., 2010; Huang, 2013; Jacobs et al., 2002). Despite the comparable and sometimes even superior levels of performance by women to those of men, ability perceptions in male-typed domains such as math, computer science, and sports remain gendered such that male students tend to express stronger self-efficacy than female students (Eccles et al., 1990; Else-Quest et al., 2010; Huang, 2013). These mean-level gender differences suggest that self-efficacy perceptions are under the heavy influence of prevalent gender stereotypes and point to the necessity of dealing with stereotype issues when designing self-efficacy interventions in gender-typed domains (e.g., Lee et al., 2021, 2020). Gender differences have also emerged in the relative weight assigned to the sources of self-efficacy information (Butz and Usher, 2015; Zeldin et al., 2008). Compared to male students, female students are more strongly influenced by vicarious information and social persuasion. Modeling and encouragement by trusted family members and teachers have proved to be particularly effective in strengthening the self-efficacy of women in male-typed domains. Capitalizing on the information from social agents, therefore, can be useful for improving female students' self-efficacy (Lee et al., 2020).

The culture in which individuals reside is closely associated with self-construal (Markus and Kitayama, 1991) and thus affects the way they shape their self-efficacy. For instance, compared to learners in Western countries who tend to overestimate their confidence, learners in Eastern countries report relatively modest levels of self-efficacy (Klassen, 2004). However, this lower level of self-efficacy by East Asian learners does not signify a correspondingly low level of performance; their self-efficacy is more accurate and predicts actual performance better than the self-efficacy of Western students. As was the case with gender, the relative weight given to self-efficacy information sources also differs across cultures (Usher and Weidner, 2018). In general, Western countries have individualistic cultures, featuring an independent view of the self, and Eastern countries have relatively more collectivistic cultures, espousing an *interdependent* view of the self (Markus and Kitayama, 1991). While personal mastery experiences are consistently the most influential source of self-efficacy information across cultures, learners from collectivistic cultures, compared to those from individualistic cultures, depend relatively more heavily upon social factors such as group mastery experiences and social support (Ahn et al., 2016; Klassen, 2004; Usher and Weidner, 2018). Further differences in the relative importance of different socializers even within similar cultures have also been witnessed (Ahn et al., 2016).

Motivational, behavioral, and achievement consequences of self-efficacy

Self-efficacy operates as a core contributor to motivation and a facilitator of learning and performance. It is not merely a "passive foreteller" but an "active producer" (Bandura, 1997, p. 38) of performance such that firm assurance or self-doubt about one's ability alters how people think of, feel about, and approach a given task, easily overriding the existing skills (Bandura, 1989; Zimmerman, 2000). To date, significant associations between self-efficacy and diverse academic outcomes have been established across a wide range of learners and domains (e.g., Multon et al., 1991; Rottinghaus et al., 2003). Among diverse self-constructs, self-efficacy is arguably the strongest predictor of subsequent motivation, engagement, and performance in the cyclical self-regulatory processes (e.g., Schunk, 1991; Zimmerman, 2000). Below we describe some of the most representative outcomes of self-efficacy in academic situations.

First, self-efficacy predicts goal pursuits. It can lead learners to set different levels of goals and adopt different types of achievement goals (Bong, 2005). Learners tend to set more challenging goals and also pursue approach-oriented achievement goals when they feel confident about their capability to perform tasks successfully. Self-efficacy predicts higher goal-settings, which in turn lead to better self-regulation and performance (e.g., Brown et al., 2011; Lee et al., 2014; Zimmerman et al., 1992). According to meta-

analyses examining the relations between self-efficacy and achievement goals (e.g., [Cellar et al., 2011](#); [Huang, 2016](#); [Senko and Dawson, 2017](#)), self-efficacy also shows moderately positive relationships ($0.29 \leq \bar{r} \leq 0.45$) with mastery-approach goals (i.e., aiming to improve competence and to master the learning tasks), which are the most adaptive form of achievement goals. Although the effect size is smaller than that observed with mastery-approach goals, self-efficacy also relates positively ($0.04 \leq \bar{r} \leq 0.30$) to performance-approach goals (i.e., aiming to demonstrate competence and to do better than others), which are usually associated with higher achievement. Self-efficacy generally demonstrates negative or non-significant relationships ($-0.18 \leq \bar{r} \leq 0.00$) with performance-avoidance goals (i.e., aiming to hide incompetence and to avoid doing worse than others), which are the most maladaptive form of achievement goals in terms of motivation and academic performance. Therefore, feeling self-efficacious helps learners to set and pursue adaptive goals when embarking on the self-regulatory process of learning and performance.

Second, self-efficacy is strongly associated with academic emotions experienced in achievement settings. While perceived physiological and affective states function as a source of self-efficacy ([Bandura, 1997](#)), self-efficacy can further evoke positive or negative emotions relevant to achievement pursuits such as interest ([Bandura and Schunk, 1981](#); [Bandura, 1982](#); [Rottinghaus et al., 2003](#)) and anxiety ([Bandura, 1988, 1989](#); [Nie et al., 2011](#)). Learners who are confident in performing a task are likely to experience feelings of interest and actively engage in the task with enjoyment; learners who doubt their capability to perform the task are likely to experience feelings of anxiety and the urge to avoid the task. Strong self-efficacy increases interest through a sense of causal agency in bringing about the desired outcome and experiencing anticipated satisfaction from the success ([Bandura, 1997](#)); weak self-efficacy induces high levels of anxiety and stress through apprehensive thoughts about their deficiencies to cope with the task demands and the negative outcome should they fail ([Bandura, 1988](#)). Other emotions may also accompany self-efficacy ([Pekrun, 2006](#); [Shao et al., 2020](#)). For example, individuals with strong self-efficacy to achieve positive outcomes or avoid negative outcomes can experience anticipatory joy or anticipatory relief, respectively, through the perceived control over the outcome. Individuals with weak self-efficacy may experience hopelessness and frustration due to the perceived ineffectiveness of their effort.

Third, self-efficacy activates motivated behaviors such as choice, engagement, and use of self-regulatory strategies, consistent with what [Bandura \(1997\)](#) originally postulated in his social cognitive theory. Along with value in the expectancy-value theory ([Wigfield and Eccles, 2000](#)), self-efficacy functions as one of the two proximal determinants of academic choice and behaviors ([Bong, 2001a](#)). Learners choose to pursue their education and career paths in the domain in which they feel competent ([Hackett and Betz, 1989](#)). Even when individuals perceive high value in a certain domain, their perceived inefficacy to succeed in that domain can deter them from entering the domain. Self-efficacy also energizes individuals to invest behavioral and cognitive effort and persist in the face of difficulties and obstacles. Numerous studies have shown the significant effect of self-efficacy beliefs on academic engagement and persistence (e.g., [Linnenbrink and Pintrich, 2003](#); [Komarraju and Nadler, 2013](#); [Schunk, 1989](#)), with moderate effect sizes ($0.17 \leq \bar{r} \leq 0.48$) between self-efficacy and persistence in meta-analyses ([Multon et al., 1991](#); [Robbins et al., 2004](#)).

Regarding strategy use, self-efficacy positively predicts the use of adaptive strategies and negatively predicts that of maladaptive self-regulatory strategies. For example, learners with high self-efficacy tend to engage more in adaptive help-seeking and less in avoidant help-seeking because they worry less about showing their lack of ability by asking for help from others ([Ryan and Shin, 2011](#)). Besides, learners with lower self-efficacy are more likely to expect the worst outcomes in achievement contexts, making excuses for their potential or actual failures, cheating on academic tasks and tests to appear able, and putting off important academic tasks with no good reason ([Lee et al., 2014](#)). Meta-analyses have shown negative correlations of medium size ($-0.44 \leq \bar{r} \leq -0.38$) between self-efficacy and procrastination, indicating that people often procrastinate simply because they do not have the confidence to carry out the task. Self-efficacy enhancement can provide one effective way of treating this maladaptive procrastination ([Steel, 2007](#); [van Eerde, 2003](#)).

Fourth and most important, self-efficacy is a powerful predictor of eventual performance. Learners who firmly believe that they can succeed at a designated task perform better than those who do not ([Bandura, 1997](#)). As “a generative system of human competence” (p. 37), self-efficacy enables individuals to recruit and integrate the necessary subskills to perform a given task effectively. As reviewed earlier, it affects important cognitive, emotional, and behavioral outcomes that in turn contribute to higher achievement. Out of 50 antecedents that include cognitive ability and prior performance measures, self-efficacy has emerged as the strongest predictor of college students’ achievement ([Richardson et al., 2012](#)). Meta-analyses of studies on the association between self-efficacy beliefs and performance have covered extensive breadths and types of achievement, including academic achievement ([Honicke and Broadbent, 2016](#); [Multon et al., 1991](#); [Richardson et al., 2012](#); [Robbins et al., 2004](#); [Stajkovic et al., 2018](#)), memory performance ([Beaudoin and Desrichard, 2011](#)), language proficiency ([Wang and Sun, 2020](#)), creativity ([Haase et al., 2018](#)), sports performance ([Moritz et al., 2000](#)), and work-related learning ([Sitzmann and Ely, 2011](#)) and performance ([Brown et al., 2011](#); [Stajkovic and Luthans, 1998](#)). All meta-analyses have shown positive relationships of small to medium effect sizes ($0.10 \leq \bar{r} \leq 0.59$) between self-efficacy and performance, supporting the exceptional predictive utility of self-efficacy.

Measuring self-efficacy

Among many distinctive qualities that self-efficacy beliefs possess, the hallmark is arguably the highly context-specific nature of this construct ([Bandura, 1997](#); [Pajares, 1996](#)). Context-specificity encompasses domain-specificity, content-specificity, or measurement specificity but is not equal to any one of them. Self-efficacy beliefs can be assessed at varying levels of specificity that are most consistent with the investigators’ explanatory and predictive goals ([Bandura, 1997](#)). Learners hold self-efficacy beliefs that are skill-specific (e.g., self-efficacy for solving two-digit addition problems), task-specific (e.g., self-efficacy to perform well on the next algebra quiz),

or domain-specific (e.g., math self-efficacy). Academic self-efficacy is frequently assessed at the skill-specific level not because it is useful only at those minute levels but because researchers are often interested in predicting students' impending performance on those particular classes of tasks (Pajares, 1996). Depending on what it is that the researcher is most interested in forecasting, self-efficacy may be assessed at increasingly more general or increasingly more specific levels (Bandura, 1997; Bong, 2001b; Bong and Hocevar, 2002).

When self-efficacy items are developed to predict some concrete outcome, the assessment must emulate the content, scope, and difficulty levels of the prediction target to a sufficient degree. Otherwise, the accuracy of prediction suffers. For instance, Pajares and Miller (1995) asked a group of college students to report their self-efficacy for solving a set of specific math problems, completing everyday math tasks, or performing successfully in math-related courses. Students' math problem-solving performance and their choice of math-related majors comprised the two prediction outcomes. Although the three self-efficacy scores correlated positively with one another, students' self-efficacy ratings made against the specific math problems were the strongest predictor of their performance on the same set of math problems; students' self-efficacy ratings toward the math courses were the strongest predictor of their choice of math-related majors. The predictive utility of self-efficacy beliefs is maximized when they are estimated in reference to the tasks and contexts that best correspond to the criterial variable (Bandura, 1997; Bong, 2002; Pajares, 1996).

The key in self-efficacy assessment, therefore, is to capture the competence belief that individuals recruit as they enter the performance situations (Pajares, 1996). To measure self-efficacy in a context-specific fashion, important features of the tasks and achievement settings that could affect the quality of outcomes should be represented in the respective items and scales (Bandura, 1997). Successful performance at a broader level (e.g., writing an essay) requires more than a simple sum of specific requisite skills (e.g., spelling, grammar, punctuation, development of topic sentences, organization of ideas) and accompanies a unique set of situational affordances and constraints (e.g., themes, timeline, word limit, individual vs. collaborative work). Even when individuals feel highly confident about their capability to successfully perform each of the subskills, they could nonetheless remain skeptical about their ability to effectively execute the ultimate performance because doing so depends on the dexterous integration of all required subskills. For this reason, the correlation coefficient between any two self-efficacy measures decreases as the difference in the levels of specificity associated with these beliefs increases, even within a single domain (Bong and Hocevar, 2002; Bong, 2001b). Not only are individuals able to discriminate between their self-efficacy beliefs across multiple levels of assessment specificity, but they also rely on different cues and apply distinct self-evaluative schemes when appraising their sense of efficacy at different levels. To conserve the context-specific and generative nature of self-efficacy judgments, the complexities of performance situations should be closely mirrored in the corresponding assessments.

Promoting self-efficacy of learners

As self-efficacy plays a central role in motivating learners and actualizing their potentials, strategies to improve learners' academic confidence in their capability to learn and perform well have received much attention. In particular, various attempts have been made to promote learners' self-efficacy by manipulating the sources of self-efficacy information. Self-efficacy interventions could be classified into those involving goal setting; modeling and strategy training; evaluations and reward structures; and attributional feedback (Lee et al., 2020). We introduce several self-efficacy enhancing strategies with demonstrated utility within this categorization.

First, setting certain types of goals is beneficial for bolstering self-efficacy. Specific and proximal goals are more effective than general and distal goals because they appear relatively easily attainable. Specific goals also function as clear standards for evaluating performance, making progress and mastery along the way visible to learners (Schunk, 1990). Bandura and Schunk (1981) have demonstrated the benefits of having a specific goal with proximal subgoals in promoting self-efficacy toward solving math problems for children who initially suffered from poor arithmetic performance and a lack of confidence (see also Schunk, 1983a). The children displayed not only stronger self-efficacy but also enhanced interest and problem-solving performance. Self-set goals can also promote self-efficacy. When learners set the goal for themselves, they tend to establish a more feasible goal, consider it more achievable, and commit to and engage in it more strongly, which can further enhance their self-efficacy (Schunk, 1985). Goals that are attainable yet slightly challenging can lead to greater mastery experiences once they are accomplished. Scaffolding can contribute to self-efficacy enhancement by helping learners experience success in achieving challenging goals (Sun and Hsu, 2019). Trying to reach goals that are specific, proximal, and realistic yet demanding helps learners appreciate their progress and build positive beliefs in their capability.

Second, modeling and strategy training can boost self-efficacy by teaching learners how to succeed on a task. When learners lack requisite skills and knowledge, efficacy-building strategies such as social persuasion that do not involve actual improvement in their competence would prove futile. Learners will become confident when they receive specific instructions on concrete learning and self-regulatory strategies that work. Schunk and Cox (1986) illustrated how training children with learning difficulties in the strategy of explicit verbalization increased their self-efficacy and math performance. Combining modeling with strategy training can be even more effective because it shows how to use the strategies and simultaneously conveys the indirect message to learners that they can do it too (Schunk, 1986). Models that are perceived as similar to themselves can amplify the positive influence of this vicarious message. Schunk and Hanson (1985) compared the effects of different types of models on the improvement in math problem-solving self-efficacy and skills among children who initially exhibited low performance. Observing a peer model resulted in the greatest gain in their self-efficacy and performance. Observing a teacher model was the next most effective, which was, in turn,

more effective than not observing any model. These results corroborate the importance of model similarity as a partial determinant of the modeling effect. Direct teaching and modeling of effective strategies are thus one of the surest ways to develop a stable sense of confidence among learners.

Third, types of evaluations and reward structures are other important considerations when trying to raise learners' self-efficacy. Criterion-referenced and self-referenced evaluations offer a clear advantage over norm-referenced evaluations. The standard in norm-referenced evaluations is the performance of others (Popham and Husek, 1969). Such a standard is unpredictable, not consistently tied to one's performance, and perceived as out of one's control, making learners frustrated and disoriented particularly when they fail. In contrast, the standard in criterion- and self-referenced evaluations is unambiguous, directly tied to one's performance, and hence within one's control. In criterion-referenced evaluations, learners understand what objectives to meet and to what extent; in self-referenced evaluations, learners strive to perform better than their previous performance. Both types of evaluations provide learners with information on their current levels of mastery and progress so they can focus on improving the needed skills and competence. The two evaluations can thus function as progress feedback, communicating to learners the degree of their mastery and improvement that directly feeds into their perceptions of self-efficacy (Bandura, 1997; Schunk, 1982). The relative effectiveness of a criterion-based, self-referenced evaluation to a norm-referenced evaluation has been observed reliably (e.g., Chan and Lam, 2010; Shih and Alexander, 2000). The manner with which rewards are given can also make a difference in self-efficacy development. Rewards are most effective when they are tied to one's actual performance, thus signifying the mastery or progress on a task (Cameron et al., 2005; Schunk, 1989). When the effects of rewards for performance, rewards for participation, and unexpected rewards were compared, those for performance resulted in the largest increases in the engagement, actual skills, and self-efficacy of learners (Schunk, 1983b).

Last, healthy attributional feedback improves learners' self-efficacy. Aside from direct evaluation, teachers and parents often provide learners with various attributional feedback for their achievement outcomes, which conveys efficacy information. According to attribution theory (Weiner, 1979, 1985), success and failure can be attributed to diverse reasons, most notably ability, effort, difficulty, or luck. Attributing their academic outcomes to external factors such as task difficulty and luck would not affect learners' self-efficacy as much as would attributing the same outcomes to internal factors. By comparison, making success and failure attributions to ability, an internal factor, increases and decreases learners' self-efficacy, respectively, because ability is often considered stable in nature and hence expected to wield a continued influence on future outcomes.

Attributing failures to a lack of effort instead of a lack of ability can help maintain learners' sense of efficacy. Yet, caution is required when encouraging effort attributions for academic outcomes. When past accomplishments are attributed to effort, suggesting that learners have done well through their hard work, it can increase not only their self-efficacy but also their engagement in subsequent learning and actual skill acquisition (Schunk and Cox, 1986; Schunk, 1981, 1982). Effort attribution also promotes a growth mindset, a belief that ability can be developed through effort and the use of effective strategies, which protects learners' motivation upon failures (Yeager and Dweck, 2012). However, when failures and difficulties are blindly attributed to effort, learners can question the validity of such attribution and start questioning their ability (Schunk, 1981). This scenario is especially likely when learners believe they have invested enough effort but still could not experience satisfactory progress or task mastery. For children who are old enough to believe that high effort compensates for low ability (Nicholls and Miller, 1984; Nicholls, 1978), blaming the lack of effort for their failures might be interpreted to mean that they do not possess the ability to succeed. The potential backlash of effort attribution can intensify in contexts where one's performance is being compared to that of others (Nicholls, 1984). Under these circumstances, attributing failures to the use of inadequate strategies rather than a lack of effort could help maintain learners' self-efficacy beliefs.

Concluding remarks

Bandura's social cognitive theory features an agentic view of human functioning. From this viewpoint, individuals are not passive creatures that are under the control of environmental forces but active organisms that exercise control over their behaviors and environments in pursuit of their goals. At the core of these self-regulatory processes lies self-efficacy. The subjective conviction that one can successfully execute the course of actions required to achieve the desired goal enables the person to regulate their own cognition, motivation, and behavior. During the past four decades since Bandura proposed the concept of self-efficacy, more than enough evidence has accumulated on the critical role of self-efficacy in diverse spheres of life. While available findings have already established self-efficacy as a key foreteller of individuals' motivation, learning, and performance, continued research on this important construct will deepen our understanding of effective human functioning even further.

On the contexts of learning

This article views the context of learning through several different lenses. The first is the general distinction between learning that happens in the informal context of the lifeworld contrasted with the formal or institutionalized learning of programs, curricula and syllabi—called “education.” The second lens is the social functions of both informal and formal learning, focusing on the role of education for working life, personal life and public life. Cross-cutting these three contexts, we discuss the increasing significance today of social diversity and digital tools for meaning-making. In the section that follows, we explore the dimensions of learner diversity, and the connections between lifeworld differences and the learning that happens in formal education. A fourth area of focus is the changes that have occurred in recent decades in the media applied to education, with particular attention to the rise of e-learning ecologies. In a final section, we move in the other direction, from education back into its context to address the question with, how and in what ways can learning be a force for educational justice and social change?

Learning in formal and informal settings

“Context of learning” refers to the environment in which learning occurs. Education is a process and profession that must be understood by the influences of context. Its work is oriented to that context. It serves purposes located beyond itself, in context.

In this article, we reflect upon contexts of education as we move into the middle decades of the 21st century, when formal education seems more important than ever before. Politicians talk about the knowledge society; business people discuss the new economy; and parents worry about the role a good education will play in their children’s futures. Despite this, educators struggle with the resources available to them as they attempt to meet increasing expectations of the social context in which they work.

Going back to the fundamentals, what is this process, “education,” that is expected to do so much? In its most visible manifestation, it consists of institutions: schools, colleges and universities. Education also occurs in workplaces, museums, communities, outdoors and a myriad of other places, both formally and informally. Broadly conceived, education is a social process, a relationship of teaching and learning, where one person supports another to learn, and to learn how to learn.

Learning refers to the process of familiarizing with and understanding new things. This can include knowing about a specific idea or object and knowing how to act under particular circumstances. Humans are in their nature highly capable of learning at all stages in their lives. They constantly learn in an informal way simply by immersion in their lifeworld. This happens through the rich surroundings and the people (peers, older children, adults) who have an innate social inclination to teach those around them in an informal way, as well as to learn from them (Kalantzis and Cope, 2012).

In the formal domain of learning, since the rise of mass-institutional education the focus of education has primarily been cognitive, and more specifically the ability to retain empirical knowledge and application of routines for the application of mental procedure in long-term memory (Kirschner et al., 2006). However, by focusing on the mind of the individual, we are disregarding the knowledge that exists in the social environment. John B. Watson, the father of behaviorism, had suggested to bring the focus of learning on the activity that occurs in the context of an environment (Cope and Kalantzis, 2020b). Nevertheless, behaviorism has been the focus of much criticism for the mechanical and disciplinary character of its core stimulus-response notion.

Formal education consists of the knowledge acquired through an educational institution (from preschool to graduate school), which is organized, structured and goal oriented (Kalantzis and Cope, 2012; Raikou and Karalis, 2010; Schugurensky, 2000; Melnic and Botez, 2014). Formal education follows a concrete curriculum, with specific objectives, content and methodology (Melnic and Botez, 2014). Its learning is systematic and deliberate (Kalantzis and Cope, 2012) and usually results in the acquisition of quantifiable credit, a certificate or a diploma.

However, much of our knowledge has been acquired by interacting with people other than our formal instructors and outside of school. Informal learning is not restricted to a specific place, time or age. It happens in our everyday life, at home, with our family, at work, at a library or a market, when we are with our friends. Most of the time we do not even realize that we are learning (Kalantzis

and Cope, 2012). Informal learning does not follow a specific curriculum and it is usually characterized as an experiential learning process (Strimel et al., 2014). It can happen individually or when being part of a group (Schugurensky, 2000). Some examples of informal learning activities are: visiting a museum or an exhibit, listening to the radio or watching TV, reading magazines and newspapers, using the social media (Facebook, Twitter, Instagram, etc.), attending conferences, traveling, meeting new people, living in a foreign country, etc. Informal learning is usually spontaneous and incidental (Melnic and Botez, 2014). It addresses the world around us by immersion in the experiences that are literally in front of our eyes (Kalantzis and Cope, 2012) (Fig. 1).

Schugurensky (2000) categorizes informal learning into three types, based on forms of intentionality and awareness. The first type is self-directed learning, which happens when individuals learn something intentionally, but without the presence of an instructor, and they are conscious of their learning result. The second type is incidental learning, and it happens when an individual learns something from an experience they had, without doing it on purpose, but by realizing in the end that they had acquired some new knowledge. The third category is socialization, which occurs through interaction with other people in our everyday life, without doing it on purpose and without understanding that we are learning something. Sometimes, we may become aware of such social learning later in life, when thinking of our previous acts and our beliefs.

The social functions of education in context

Formal learning or education prepares people for productive working lives. Education also has an important role to play in the development of responsible citizenship. Together, these two foundational functions link education to its context by developing learners' capacities for social participation.

To take the first of these contextual objectives, work has changed enormously since the introduction of mass-institutionalized education in the 19th century. These changes have been characterized by transitions from "Fordism," "post-Fordism" to the "information economy." In transition, the nature of work has changed: technology, management, workers' education and skills, and markets and society. Workers of today need to have acquired quite different skills and sensibilities from those of the past (Kalantzis and Cope, 2012).

In the area of citizenship, the modern state takes considerable responsibility for education, much of which is public or at least partly supported by the state. Education plays an important role in shaping certain kinds of citizens. The nature of citizenship is changing just as dramatically as that of work over the past century. Modern, mass, institutionalized schooling emerged in an era characterized by nationalism in the public sphere. Large and strong states established command relationships with their citizens. These states promoted the idea of a homogeneous community with clear borders. Schools played an important role in this process as they became one of the primary places for the socialization of children—using didactic teaching and taking an exclusionary or assimilationist approach to learners' differences.

Since the last quarter of 20th century, we have entered a phase referred to as "neoliberalism," during which the size of the state has been shrunk and an ethics of the free market and self-reliance revived from its 19th-century roots. This has translated into a partial withdrawal of the state from education and increasing pressures for the privatization of education. We have also reached the point of a global environmental and climate crisis which is becoming harder to ignore.

"Civic pluralism" is a strategically optimistic reading of contemporary trends. It describes and prescribes a system of distributed governance and responsible citizenship—in workplaces, community organizations and schools, for instance. Civic pluralism involves continually negotiating differences and problem solving, frequently supported these days by digital media. For this social context, education for civics fosters capacities to participate based on an ethic of self-governance and participation. It is environmentally aware, striving for sustainable solutions to the challenge of meeting human needs. Today, an important new set of capacities is captured by the notion of "digital citizenship," covering everything from participation in classrooms and self-organizing online communities, to digital democracy more widely conceived as a formal system of social governance (Kalantzis and Cope, 2012).

Fig. 1 The lifeworld context of learning.

The challenges of these changes in social context require that schools broaden and deepen their educational objectives. Among the touchstones for the next generation of educational environments are pedagogies that inspire critical, creative and design thinking. In such environments educators will strive to achieve equality without demanding sameness. These are ambitious goals, but the collaborative and intelligent tools of our era of e-learning make these large educational aspirations at last practicable.

Among the two most important social transformations of recent times have been the increasing recognition of lifeworld diversity and the rise of digitally-mediated communications (Fig. 2). These have had substantial impacts upon all aspects of working, personal and public life.

In the following sections of this article, we are going to focus on these enormously important, complex and frequently vexed dimensions of the contemporary educational context: learner diversity and digital technologies.

Learner diversity as a major contemporary contextual factor

In its earlier phases, mass-institutionalized schooling attempted to avoid, ignore or over-write one of the key aspects of its context: learner diversity. This encompasses: material conditions (social class, locale and family); corporeal attributes (age, race, sex/sexuality, physical and mental abilities); and symbolic representations (language, ethnos, communities of commitment). These factors shape the learner's personality. They also have an enormous impact on their engagement with learning and their educational and social outcomes.

Historically, education has managed its context of human diversity by exclusion (e.g., separate schools), assimilation (e.g., one-size-fits-all, sink-or-swim education), or more recently and aspirationally, practices of inclusion. Inclusive educators will negotiate the uniqueness of every learner's lifeworld context, and the fluidity of life in a time of intense social change. Inclusive schools ensure that their institutional organization and pedagogical practices make it possible for all members of the learning community to belong and achieve, in their difference.

Each of these dimensions of diversity has over the past decade been in a process of transformation, both of our understandings and the way in which schools and society negotiate these differences (Kalantzis and Cope, 2016b). Age differences are being transformed as the nature of childhood, adolescence, adulthood, and aging are shifting, and education is expanding its scope across the lifespan. "Race" is coming to prominence with increasing consciousness of the impacts of racism on educational opportunities. Sex and sexuality are recognized to be non-binary, with a large range of variation across LGBTQ, transgender/cisgender, and other alternatives, raising issues that schools have traditionally avoided or ignored. Physical and mental abilities are no longer considered straightforwardly as dis-abilities, but as embodied potentials and neurodiversity. In the era of mainstreaming, educators need to ensure equitable access by means of differentiated strategies. In the area of culture, students increasingly live their everyday lives in affinity communities, whose distinctiveness is frequently magnified by social media. Racism and sexism take new forms in the era of cyberbullying and pervasive microaggressions. Language differences and pedagogies are addressed in new ways with ubiquitous translation tools. First Nations' perspectives also need to be an integral part of contemporary education, including Indigenous pedagogies that contain insights of value to all learners in times of ecological crisis and social uncertainty. Meanwhile, social and regional inequalities are becoming more pronounced, complicated by the intersection of inequality with the other dimensions of diversity.

Fig. 2 Contemporary transformations in the contexts of learning.

“Diversity” is a neutral-sounding word, but any such neutrality hides a multitude of evils. Diversity—or in the case of education, the lifeworld differences that learners bring to school and then encounter in their schooling—is riven with inequalities. After decades of incremental redress through social programs of redistribution, by the early 1990s in almost every country of the world material inequalities had begun to expand again, returning us by the third decade of the 21st century to disparities of wealth that are as severe as those of unrestrained industrial capitalism at the end of the 19th century (Piketty, 2014; Sassen, 2014). Meanwhile, embodied and symbolic differences are as often markers of inequality as they are innocent differences, worthy of celebration. A pyramid visualization (Fig. 3) captures the contextual layers of material, embodied and symbolic differences that are always present. For every learner the whole that constitutes their identity is uniquely configured, albeit with cross-cutting historical commonalities with others. This is the “lifeworld” that the learner brings to school from their social context.

What role can education play? What impacts can it have on its context? On past experience we might, with full justification, claim that these and any other agendas of education reform can have little or no impact. What, after all, can education do to influence its social context? What is the potential of education to redress inequality?

Any such project must start by addressing what we have termed “material differences.” More egregious than any of the differences in societies that profess democracy and to offer equal opportunities (at least, if not equal outcomes), are differences in resourcing for education. In the United States, there can be a four-fold difference in the per student funding for public schools, and private schools can cost parents as much as ten times the revenue spent per student on public schools. This is without the differential access to family-funded learning opportunities, from books, to smart toys, to digital devices, to private lessons, and such like. This inevitably produces a spectrum of embodied “abilities,” measured less these days by intelligence tests than standardized tests of domains of knowledge. In the realm of symbolic capital, this translates into a series of capacities to survive the rigors of the modern world captured in the notion of “episteme.” But the differences start—prosaically, and incontrovertibly in the relation of resource inputs to educational outcomes. Along the way, the differences are refracted through specific histories of systemic discrimination such as racism and sexism, but level of education stands out above all other demographic variables as a predictor of social outcomes.

In their book, *Deaths of Despair and the Future of Capitalism*, Princeton University economist Anne Case and Nobel Prize winner Angus Deaton argue that having a bachelor’s degree or not, is a more precipitous dividing line than race or gender when measured in terms of social outcomes. Their measures are not only the 80% “earnings premium” for those with a bachelor’s degree or more, but dramatically different unemployment rates (those without bachelor’s degrees are twice as likely to be unemployed), labor force participation rates (2.5 times as likely to have dropped out of the workforce), life satisfaction (according to national surveys), health outcomes, and tragically rising adult mortality rates—what they call “deaths of despair” related to suicide, the opioid epidemic, smoking, obesity and lack of access to medical insurance and quality care (Case and Deaton, 2020).

The COVID-19 crisis magnified this disparity where, apart from age, level of education was the principal predictor of likely death—whether that was the result of underlying health conditions, or working in essential services where the luxury of shelter-in-place and work from home was not feasible (Chen et al., 2021). And while disproportionately larger numbers of Blacks and Latinx are imprisoned, by far the most significant factor predicting imprisonment is level of education. Of course, if you are Black, or Latinx, or a woman, or disabled, you are less likely to have a bachelor’s degree, and so histories of institutional racism, sexism and exclusion factor into the underlying educational injustice. However, the many whites without bachelor’s degrees do about as badly on these measures of social outcome, at times worse even. In a society and economy that today places a premium on epistemic capital, education trumps other demographics as a variable that will predict the most fundamental of social outcomes.

Speaking to the US context, Blacks, Latinx, women, and people with disabilities can do well if they have higher educational qualifications. Whites, men, and people without disabilities often do badly when their education ends at school. We must join the rage

Fig. 3 “Lifeworld” as the social context of education.

at egregious practices of racial injustice that motivate the Black Lives Matter movement, and the oppressive sexism of unequal power exposed by #metoo. Redressing these abominations is not merely symbolic matter, as if there were easy fix of recalibrating our attitudes or nodding in recognition. Nor can these agendas remain a narrowly personalized and or neatly compartmentalized into a politics of “identity.” This is because specific injustices of embodiment and symbolic representation are always sourced in and refracted through the material injustices that they re-articulate and exacerbate. In the inseparable unity of our lifeworlds, the layers can’t be peeled apart, nor can their circumstantial intersections straightforwardly be identified.

Digital media as a major contemporary contextual factor

Educators today are working in a time of great change, where the contexts of learning and conditions of social interaction are changing radically. One major factor that redefines the relation of learning to its contexts is the development of digital technologies. These have already had a significant impact on the way informal learning occurs. What will be their likely impacts on formal learning?

The current era is characterized by the abundance of information and the easy access we can have to it through the Internet. This contextual change—the ubiquity of digital media—is a major key contextual factor that is today transforming education. Indeed, applied to education, digital technologies point to perhaps the largest shift in the systems of modern education since the 19th century. Among the major dimensions of change are: configurations of space, learner-to-teacher and learner-to-learner relationships, the textual forms of knowledge to which learners are exposed, the kinds of knowledge artifacts that students create, and the way the outcomes of their learning are measured.

As a consequence of ubiquitous access to information in the era of digital media, what contemporary students (of all ages) require from their education is to teach them “how to learn” and navigate an excess of information, and not “what to learn,” since the content of the information is easily accessible. Lifelong learning and skill development are necessary to succeed in a changing society, more than the ability to remember things from school or long-term memory (Cope and Kalantzis, 2020a). This challenge could be addressed in part by integrating and/or recognizing informal learning in formal educational settings. Below are some methods in which, according to Strimel et al. (2014), informal knowledge sources and process of learning can be incorporated in formal education:

- **Use of technology:** Smartboards, smartphones, tablets and iPads, in classrooms or in the workplace can support learners to be more engaged and also can create a more personalized learning experience.
- **Social media:** Blogs, wikis, Facebook, Google, Twitter, Instagram, Skype and other media can be used by students to search information and document their learning.
- **Open educational resources (OER):** These are easily accessed and free of charge resources that can assist individuals to advance their skills and knowledge.
- **MOOCs (Massive Open Online Courses):** Open and free-of-charge courses offered to anyone worldwide who is interested in an area of new knowledge or learning a new skill.
- **Formalized coaching:** This process includes using live case studies in the classroom or workplace, during which the teacher can meet personally with each student.
- **Electronic portfolios:** This tool can be used by students to demonstrate learning outcomes.
- **Work-based learning:** Includes practicing and applying skills that are closely related to workplace.

Kraemer (2008) has defined distance learning as the process that occurs when learners and educators are in a different space or time. This idea has evolved over the years considering the influx of digital technologies in learning contexts. New terms have appeared, such as online learning, e-learning, open learning, blended or hybrid learning (Blake, 2009). Oblinger and Hawkins (2005), Dublin (2003), Holmes and Gardner (2006) point out that there is not a universal way of defining e-learning. Arkorful and Abaidoo (2015) claim that e-learning refers to the facilitation of learning through the utilization of digital technologies. Therefore, the term can include distant, fully or hybrid online courses that are realized through the use of the Internet (Gotschall, 2000; Maltz and Deblois, 2005) or learning through the use of information and communication technologies as a complement to traditional, online or hybrid learning (OECD, 2005). In our definition, online learning can be considered any learning interactions supported by connected digital devices. Thus, online learning is not just a synonym for remote learning; it can also involve both in-person learning with online support and remote learning online.

In the phrase “e-learning ecologies,” the metaphor “ecology” is used for learning contexts that could be considered as ecosystems, which involve the complex interaction of human, textual, discursive and spatial dynamics (Cope and Kalantzis, 2017). Such e-learning ecologies can play a critical role in the evolution of modern education. However, digital technologies can also reproduce traditional pedagogical modes, resulting in minimal transformational impact on the substance of pedagogy. What changes are possible in the relation of education to social context as a consequence of new educational technologies?

Applied to education, digital technologies can be used as a force for reform. On the other hand, we may introduce a whole lot of technology into schools, and yet nothing changes in institutional or pedagogical senses. Educational technologies may bring to life again, and reproduce, traditional relations of learning—sometimes with justification, but other times representing a step back. Technology is pedagogically neutral. It can be a force for change, but it can also be used to reproduce old practices.

The affordances of the digital, however, can be harnessed to create learning ecologies that are more engaging for learners, more effective and resource efficient, as well as a more equitable response to learner diversity. Here are seven affordances of the digital that can be utilized in support of learning, be that in-person, blended or remote.

1. **Ubiquitous Learning** refers to learning anytime, anywhere, anyhow. This affordance connects with the concept of informal learning, which can happen in every aspect of our life, no matter the time or the location. The use of new digital and web-based media has enabled the realization of this affordance, by giving the opportunity to learners to learn without any physical or time restrictions. Especially during the COVID-19 pandemic, this approach suddenly became the new normal, as in-person contacts were limited and thus, for almost 2 years, intermittently in different places around the world, people were learning remotely.
2. **Recursive Feedback** is a version of formative assessment, or continuous feedback that is constructive to learning. Based on the concept of reflexive pedagogy, students nowadays should get feedback on their performance while they are still in the process of learning. This will help them to target any areas that need more effort, and they will all end up achieving “mastery” (Bloom, 1968), thus achieving better learning outcomes. This feedback can be in the form of peer comments, machine responses, teacher comments, as well as self-reflection (Pinheiro, 2020).
3. **Multimodal Meaning:** This affordance addresses the use of various forms of meaning, like images, videos, audio, text, diagrams, data, etc. at the same time and in various combinations to enhance the meaning of the topic addressed and create richer knowledge representations and communication. This new type of multimodal meaning making encompasses genres observed in social media, websites, apps, infographics and data visualizations. Its benefit from the educational perspective is that it prompts learners to think about the form of their text and also diversify and broaden options for knowledge representation for a broader range of learners.
4. **Active Knowledge Making:** This refers to the design of meanings and the creation of new knowledge in the learning process. The idea encompasses the process where learners are positioned as knowledge producers and meaning makers. They co-create knowledge through a scaffolded process guided by the instructor. This concept introduces a change in the balance of agency in the learning context, where students are positioned as active participants of the learning process.
5. **Collaborative Intelligence:** This affordance concerns the process where learners draw down and acknowledge social knowledge, instead of memorizing it as if it were straightforwardly and individually theirs. In our everyday life, we have access to millions of sources that provide information to our queries. Thus, instead of trying to memorize all these sources, we only have to source them when needed. This practice leads us to the idea of knowledge collaboration and social learning. Since knowledge can be reached through a few steps in our digital devices, we should aim in developing skills about how to collaborate in this new setting, by creating knowledge, making it available to other learners and also, using appropriately the work of others. This practice represents a shift in contemporary ways of dealing with knowledge in the digital era and evolving learning contexts.
6. **Metacognition:** This refers to thinking about thinking, a learner thinking about what they have learned, in what way, what steps or methodology they followed, what they have acquired in comparison to their previous knowledge, and what goals they have achieved. This process corresponds in some sense with self-reflection, while it also focuses on the learning process and the disciplinary practice. The literature suggests that this process improves learner performance (Bransford et al., 2000) and that is why it is considered an attribute that needs to be valued in a contemporary learning context.
7. **Differentiated Learning:** This notion targets the different needs and interests that the students bring from the context of their lives to a learning situation. Digital technology systems can easily address these context-dependent factors, because of the adaptability and flexibility they offer. In recognition of contextual variation, learners can work at their own pace, dealing with content personalized to their level, without restrictions of space and time. Each student learns according to their interests and needs, and they bring to the learning process diverse perspectives that prompt deeper discussions. In the process of learning through digital tools, learners can work on different things at the same time or on the same thing, but at a different pace. In an equitable and inclusive education, they no longer need to be doing the same work at the same time, on the same metaphorical page.

Looking forward to a new wave of digital technologies, what might be the impact of might “artificial intelligence” (Cope and Kalantzis, 2016; Cope et al., 2020)? Artificial intelligence is profoundly different from human intelligence but offers the potential to transform learning contexts in ways that, paradoxically, can make them more human. Artificial intelligence is often identified by its methods, and it is assumed that the outcomes of these calculations can become more human, through machine learning, deep learning in neural networks, and perhaps, quantum computing in the future (Cope and Kalantzis, 2020a). However, these methods are only calculations and the question that rises is how they can support human meanings?

Since digital technologies can represent and communicate sound, text, speech and image, digital tools can act as “cognitive prostheses” and expand our capacities to make meaning. They function as a substitution for long-term memory and provide supplementary tools for reasoning. There is no value in repeating cognitive processes from memory when apps can work on them for us. However, there is value now on the ability to use these apps and digital devices to access social memory. Therefore, the learning contexts today should be designed on the basis of the sociability of knowledge.

To give a practical sense in this theoretical notion of cognitive prostheses, we mention one of the recent projects we are working on at the University of Illinois within the domain of language learning. We have created an app within the social learning platform CGScholar, where pairs of native speakers (Greek–English and Spanish–English) work together on each other’s written language, creating and offering each other scaffolded, machine-supported formative feedback on multiform representations and communication (Cope et al., 2020). The research aims for further improvement of the digital tools and their application in language learning

classrooms. At the same time, this is a practical example of putting “cognitive prostheses” to work, where human-technology interaction has become an integral part of the communicative and learning repertoire of humans. Students in this context are encouraged to learn how to use digital tools effectively in their everyday lives, in this case to facilitate communication in peer language learning. In this learning environment, considering the needs of contemporary learners of additional languages, transposition of meanings on the level of languages and multimodality has central place in all the dimensions of the environment. Practically, this occurs by supporting hybrid language use between participants and using the semantic prostheses of machine translation tools as an integral part of the learning practice.

We mention these practices around the use of artificial intelligence in education in order to highlight the potential it provides for learning, as well as the necessity to be considered in a social context currently in a process of transformation as a consequence of these developments. Machine intelligence has become an integral part of our daily lives. Therefore, from the educational point of view, it is critical to do some forward thinking and consider the needs and interests of contemporary and future learners when designing and implementing a new generation of learning environments.

Addressing changing contexts in formal education

The integration of digital technologies in all aspects of society is a phenomenon that is affecting our everyday lives. However, education today, even when it uses digital media, is frequently repackaged in technically outdated and pedagogically narrow learning management systems that were designed to replicate engineers’ recall of their own school days but not to realize contemporary educational values. Among recent innovations is “personalized learning,” allowing learners to work at their own pace but at the cost of tethering them to their screens and isolating them from learning community interaction. Behavioral surveillance systems might even make old-school behaviorist educational psychologists blush. Games try to make children think that rote learning can be fun, but the kids know that “real” games are much more fun. Relentlessly frequent online quizzes and tests are narrowly cognitivist in their orientation, mostly measuring memory of facts and correct replication of operations. Applications of artificial intelligence to education bring the perils of inhuman automation, surveillance and profiling that produces a new and often invisible tracking, along with commercial ownership of personal education data and digital identities (Cope and Kalantzis, 2015a,b).

Beneath these practices of pedagogy, schooling continues to serve and even to amplify social inequality. The school insists on inequality so long as its systems rely on summative and norm-referenced assessments. Learners are brought into the class with the expectation that all can perform, but summative assessment requires that only a few excel while many do moderately, or not very, well. Aptly, the word used to evaluate the value of deceptively nearly correct, trick items in select response assessment theory is “discrimination.” With a cognitivist and individualist focus, the mediocre and poor performers are left to blame themselves for what they might suppose to be a lack of intelligence or ability. Schooling legitimates a dishonest meritocracy, because in “real” life those who succeed on measures of wealth and power are not necessarily terribly meritorious. The few who succeed do so because the system—including the education system—is rigged in their favor. This is how the outcomes of schooling come to be as unfairly unequal as the larger society, and even magnify that unfairness. So, what is to be done?

The outcomes of schooling, we might term “epistemic capital.” If we navigate our way around the dangers of back-to-the-future educational media and harness their innovative and inclusive potentials, this may be our new best chance to redress the longstanding failures of schooling to achieve its social objectives of equity (a level playing field of opportunity) or progress toward equality (of outcomes). In schools, e-learning is the first big change in educational media since the widespread application in early modern times of the teacher lecture, the textbook, and the test. These discursive forms were subsequently mass institutionalized in the industrial era. Of course, things may go from bad to worse: if in discursive terms the e-textbook is just a digital version print textbook where all the students are on the same page at the same time; if the learning management system is just an online replicant of the lock-step syllabus; if the flipped classroom video is just a version of the lecture that the student quiescently watches; if the video discussion is just a version of the in-class discussion where one domineering student second-guesses the correct answer to the teacher’s question; and if the computerized test is just a reincarnation of old, summative select response and supply response tests.

Things do not have to be this way. A purposeful shift to learning analytics could offer formative feedback, where every student can succeed albeit at a pace that works for them (Dawson and George, 2014; van Haren and Harroun, 2019). Differentiated instruction could be oriented to equivalent outcomes. Scaffolded peer feedback and artificial intelligence could be designed into digital knowledge ecologies, offering extensive and timely support on a scale previously impracticable for teachers on anything more than one-to-one teaching (Cope et al., 2020). Where the old communicative artifacts of formal learning were biased toward reading and listening, textbooks and teachers, e-learning ecologies can rebalance learner agency, so every student spends as much time engaged in active meaning making as “reading” those meanings, including those of their peers (Montebello et al., 2018a,b). Individual intelligence now becomes inseparable from collaborative intelligence, and instead of penalizing learners for “cheating,” we might offer “help credits” for their contributions to the learning of others and the learning community. As soon as epistemic agency is rebalanced, learner differences become visible, and these become valued and a resource for learning. An architecture of templated sameness (watching the video lecture, being on the same page of the e-textbook, marching lock-step through the learning management system, and standardized online tests) is replaced by a learning ecology of productive diversity where then differences between learners are leveraged in scaffolded peer feedback as a resource for learning (Kalantzis and Cope, 2016a).

Today’s education realities are confronting and, as educators, our responsibility is to confront them. Here, in the relation of education to its wider social context, we want to apply Nancy Fraser’s argument that justice is an intersecting politics of

Fig. 4 Toward justice pedagogy: parallel programs of redistribution (for access) and recognition (for inclusion).

redistribution and recognition (Fig. 4). Epistemic capital is a powerful determinant of social outcomes, transcending race, gender, ethnicity and other markers of privilege. Of course, race, gender, and ethnicity are crucial determinants of educational outcomes, but the demographics of outcomes tells us that education makes a crucial difference whatever the other variables. There can be no justice in education so long as the already-privileged get many more resources spent on their education than the less-privileged. Democracy promises equality of opportunity, if not necessarily equal outcomes. This is called “equity,” a project which we fall back upon when the project of equality for the moment at least seems impossible. More than ever in the era of digitization, automation and artificial intelligence, education is the pathway to epistemic capital. But its promise of opportunity for all might be classed “fake news” when the resources attributed to the development of epistemic capital are so unevenly distributed. We describe the meaning-making essence of this epistemic capital as multiliteracies and its pedagogy of access.

Of parallel significance is a politics of recognition and a pedagogy of inclusion—where the exclusionary discourse and institutional practices of racism, sexism, homophobia, and anti-elite, anti-science intellectualism are confronted in schools before they can become baked into adult consciousness. These require the development of cultures of schooling that afford dignity to diverse personhood, extend a sense of belonging to all members of the learning community in equal measure, and treat every person with respect for the unique conjunction of their lifeworld experience and sensibilities. To learn, students need to feel they belong in that learning. The learning must also create space for agency that offers opportunities for alternative paths of self-development, the outcomes of which may be different but equivalent in the scope they offer for social action and personal autonomy.

A politics of redistribution without recognition fails to the extent that it frequently misunderstands and alienates the subjects whose lives it aims to improve—this was the error of the welfare state and its one-size-fits-all, comprehensive curriculum. On the other hand, a politics of recognition without a politics of redistribution can ironically, tragically, and incorrectly be read by some as a politics of exclusion, when for instance poor whites mistakenly feel they are not getting the attention afforded blacks or immigrants. The politics of identity without a politics of material distribution has produced destructive ethnonationalist rage whose shrill voices, amplified by social media, have at times bordered on unhinged.

As for the equity agenda, in Jim Gee’s words, this may simply be a matter of “learning to ‘play by the rules’.” Equity in this sense means successful adaptation to context. However, at the same time it may also be “a way station on the route to people being pro-social agents able to innovate and transform ... for their own purposes and for the creation of a better world” (Gee, 2009: 27). Now the conversation turns to how education can be a force that can change its context.

Understanding culture	267
Why understanding cultural communities of practice is important	268
Studies of differences in pathways of learning and development across cultural communities of practice	271
References	273

In order to examine cross cultural perspectives on learning, three fundamental propositions must be interrogated. The first is how we understand culture. The second is understanding the functionality of culture in the evolution of humans as a species. And the third is understanding the role of diversity in cultural communities in terms of our evolution and survival as a species. These foundational propositions allow us to place historical studies of diversity in pathways of learning in context and to argue why such diversity is functional and important.

Understanding culture

Across fields in psychology and even anthropology, culture has been ascribed to groups of people presumed to be homogenous. Such groupings have typically included nationality, religion, ethnicity and most recently—in the last 500 years—constructions of race. There is a distinction between nationality and ethnicity. National borders historically shift based on warfare and political shifts. For example, Spain did not become a unified nation until 1492. The movements among the Catalan peoples even today around maintaining their language and even calls for separating from the Spanish state are just one example of ethnicity preceding nationality in many cases. Ethnic groups typically have longer histories than nation states. This is evident in the many different ethnic groups that either make up most nation states or that cross national borders, such as the Roma people who can be found across Europe. And it is equally important to recognize the heterogeneity within the Roma ethnic group. Race as a social and political construction is relatively recent in human history, taken up during the period of the European Enlightenment by philosophers and scientists in the physical sciences. From Emmanuel Kant and J.F. Blumenbach in the 1770s to French writer Gobineau's *Essay on the Inequality of the Human Race* in 1853 to Ripley's 1899 *The Races of Europe*, the argument that human beings could be divided into hierarchies based on skin color had become deeply established in European and US intellectual thinking. These philosophical arguments buttressed and provided moral warrants for the political and economic efforts to colonize and enslave populations from Africa and indigenous populations in the Americas and other parts of the world (Mills, 1997). Among the ironies of this system of racial classification has been the internal presumptions of social, cultural and biological hierarchies among populations presumed to be "white." For example, the English demonized the Scots and Irish even prior to their colonization efforts in the Americas, with a history of lynching that precedes such horrendous acts during the enslavement of Africans in the Americas (Dunbar-Ortiz, 2014). Ripley in his 1899 *The Races of Europe* distinguished between the Nordic races which he presumed to be superior to the "feeble-minded" lower Mediterraneans. By the 1800s scientific racism emerges with the field of craniology where scientists use measures of presumed differences in brain size among racial groupings as scientific evidence of natural superiority (Gould, 1981). In 1892 the American Psychology Association was formed with its first president, renowned psychologist G. Stanley Hall who believed in racial hierarchies. The Eugenics movement evolves in the early part of the 20th century, largely in the US, where psychology as a field takes up these assumptions of racial superiority in natural intelligence, advocated by preeminent educational psychologists such as Lewis Terman, Robert Yerkes, and Edward Thorndyke. By 1926 The American Eugenics Society was formed. By 1912 Goddard completes a study of a family of poor whites whom he argues are inferior and therefore should not be allowed to reproduce. Ironically, the Nazi regime of Germany studies the US Eugenics movement as a model for their own system of racial hierarchies. In the US who gets classified as white has shifted (Ignatiev, 1996; Williamson et al., 2007). In the US the Eugenics movement has had a profound impact on the organization of public schooling, leading to differentiated instruction or tracking associated with race and class (Tyack, 1974; Winfield, 2007). By 1969 Jensen publishes "How Much Can We Boost IQ and Scholastic Achievement" in the *Harvard Education Review* and in 1994 Hernstein and Murray publish *The Bell Curve* and in 1999 James Traub publishes "What New School Can Do" in the *New York Times Magazine*. The boundaries of who is positioned as the other, shifts. More recently, propositions around inherent deficits has generalized to what has come to be called "a culture of poverty" (Jensen, 2009; Payne, 1999). This abbreviated history of conceptions of human communities illustrates how these ideas have been taken up in philosophy, in the sciences, and indeed in the world of practice.

The point here is that constructions of cultural communities of humans is long, complex, highly contested, and its contestations deeply embedded in formal intellectual disciplines. It is important to note that contestations over presumptions of racial hierarchies and even ethnic hierarchies have been made consistently by the communities that have been demonized. DuBois (1897), Hancock (2005) as early as 1897 critiqued the very idea of race. Historians and sociologists from Carter G. Woodson to Mary McLeod

Bethune, historians from Anna Julia Cooper to Lerone Bennett and John Henrik Clarke have critiqued the construct of race as ideological and political. In psychology as a domain, for example, the field of Black Psychology has examined the impact of cultural practices among peoples of African descent as evidence of long histories of African ethnicity rather than race associated with enslavement (Akbar, 1979; Azibo, 2003; Cross, 1991; Jones, 1980).

Culture is defined in terms of routine communities of practice (Kris Gutierrez and Rogoff, 2003; Rogoff, 2003). As such, people belong to multiple communities of practice. Some communities of practice are historical and inter-generational. Such inter-generational practices often transcend national boundaries. For example, pan-ethnic groups often sustain belief systems, routinized forms of social interaction, patterns of social networking, and ways of using language that move across national borders and times. Boykin (1985) describes this phenomenon as the deep structure of culture. Peoples of African descent—on the continent of Africa and dispersed across the diaspora in Europe and the Americas—have sustained myriad shared cultural practices (Akbar, 1979; Asante and Asante, 1990; Blakey, 1998; Champion, 2003; Karenga, 2003; King, 1976; Nobles, 1972). These include respect for elders, the value of the extended family, beliefs around connections among ancestors, the living and the unborn, the centrality of rhythm in communication and expression of emotion, among others. These practices can be viewed among African descent communities around the world. At the same time, it is equally important to recognize heterogeneity within these diverse African descent communities. This is because routine inter-generational cultural practices must simultaneously adapt to changing physical, historical, economic and political circumstances.

Cultural communities of practice may be historical and inter-generational to include nationality, ethnicity, religion. People are often born into such communities, influencing how they grow up, but also may elect to disengage from those communities over time. Some cultural communities of practices are ones that you can elect to join. Others do not have porous boundaries and are ones that can only enter through birth or some defined process of initiation. There are also cultural communities that entail practices of personal interest and often require specialized skills. These may include members of sports communities, communities of practice within the arts (e.g., hip hop, European influenced classical music, readers of Harry Potter novels), or other routinely organized practices. One can also think of communities of practice associated with historical periods. For example, Elder (2018) analyzes the impact of growing up during the Great Depression in the US on generations. Today we talk about the Millennium generation. The point here is that an important starting point for conceptualizing learning and development across cultures is that any such theorizing must be rooted in an appreciation for the very complexity of the idea itself. People belong to multiple communities of practice. Such communities of practice are both homogenous and heterogenous at the same time. All such communities of practice support and socialize repertoires, tools for thinking and acting, that serve diverse functions and goals. Vossoughi and Gutierrez (2014) conceptualize engagement in and across communities of practice as movement and not as simple stable positioning.

Why understanding cultural communities of practice is important

In education, we attend to issues of culture and cultural practices as they are potentially useful in the design of environments that support ideally robust learning (Gutiérrez, 2016; Lee, 2010). Ideally the robust learning includes the holistic development of people, particularly young people. Holistic development includes cognitive, social, emotional and physical development that supports well-being. This conception of goals of human learning extends beyond simple technocratic goals of learning academic content in preparation for work as an adult. A wide range of social settings contribute to such holistic development of children and adolescents, including the immediate and extended family, routine social networks, community settings, schools, churches, and communal resources available in both the neighborhood, the town, city, or rural region and the nation (Bronfenbrenner and Morris, 1998, 2006), and indeed resources that may be available from across the world. For example, while internet access is supported or not by local and national entities, the intellectual and social resources available on the internet come from around the globe.

The foundational question is, what role does participation in cultural practices play in human learning and development? The most basic answer is that participation in cultural practices is essential to human development (Gopnic et al., 1999; Kuhl and Meltzoff, 1996; Lee et al., 2020; Meltzoff, 1988, 2013). At birth and from early infancy, infants pay more attention to human faces than objects. Babies and young children learn their most essential competencies through imitation and exploration of the physical and social environments into which they are born and grow up. These competencies include learning language, learning to read the internal states of others—human and animate—learning to use their bodies to walk and manipulate objects. They navigate learning to read the internal states of others in relation to their evolving perceptions of their own ego focused goals and needs. Infants at birth can hear all the sounds/phonemes of all human languages. However, through imitation—hearing and testing the functionality of understanding and re-producing the sounds of the language or languages they hear—their neural networks prune to home in on the language or languages of their social environment. The documentary film *Babies* provides a powerful visual representation of the universal efforts to learn the basic human expectations for the first year of life. It documents the first year of life of four babies—from Namibia, Mongolia, Japan and the US. There is no talking during the film. We only see the babies doing what human babies do. That is they engage in routine cultural practices, embedded in the social, physical and cultural environments into which they are born, to learn to walk, to manipulate, to connect with other human beings and animals (for those growing up in rural environments). It is arbitrary to argue that one form of cultural socialization is superior to another. Rather the film vividly illustrates the diversity of pathways of routine cultural practices to achieve the foundational tasks of human development, tasks inherited from our evolution as a species. It should be noted, also, although not documented in the film, that diversity of pathways for achieving foundational

competencies we need as humans includes how children born with what are typically called disabilities also adapt through participation in routine cultural practices. And indeed our adaptability as a species contributes to navigating difference. Children who are blind typically develop enhanced hearing and touch, for example. And this adaptability is an outgrowth of both biological adaptability in tandem with the development of artifacts in human communities at particular moments in historical time—for example, invention of sign language, of hearing aids, of prosthetics for walking and manipulating. The development of artifacts is embedded in cultural practices and they serve as partners, if you will, for thinking and acting. Cole (1996), drawing on Wartofsky (1973), defines this as the mediational role of artifacts.

There are now well-developed programs of research that document and illustrate the essential dialogical relationships among physiological processes that we inherit from our evolution as a species (some of which we share to different degrees with our close animal relatives), our participation in routine cultural practices (Cacioppo et al., 2000; Chiao and Ambady, 2007; Cole, 2007; Han et al., 2013; Tomasello, 1999). These dialogic relationships also include individualized characteristics that contribute to individual personality as well as individual acuties that, if exposed to appropriate cultural supports, can lead to the development of highly developed skills (e.g., musicians, artists, experts in the sports, writers, dancers, scientists, etc.). One interesting emerging area is the study of epigenetics (Russo et al., 1996). These studies illustrate how the expression of genetic markers can be moderated by participation in cultural practices, shifts in genetic expressions that can cross generations.

We understand from these studies in the neurosciences how thinking, feeling, perceptions—of the self, of others, of settings, of tasks—interact in dynamic and dialogic ways to shape what we do, what goals we set, how motivated we are to engage, and how persistent we are in pursuing goals—short and long term (Immordino-Yang and Damasio, 2007; Zajonc and Marcus, 1984). These processes—thinking, feeling, perceiving—in the mature adult have some relatively stable dimensions, but are also highly malleable depending on the processes entailed in the routine cultural practices in which we participate (Rudman et al., 2001). This means that as we consider how participation in routine cultural practices can contribute to robust learning environments, we want to understand the following (Cantor et al., 2018; Osher et al., 2018): how micro-level interactional processes, along with the availability and functionality of artifacts in such settings, support a complex understanding of cognitive processes required for the task(s) at hand; how they support feelings of belonging and safety; how they recruit perceptions that people bring around who they are, what they are capable of, how relevant they view the tasks and the demands of participation, and how they relate to people in the environment. It is equally important to understand or at least consider what people learn around these psychological processes in one setting as they are relevant to other settings, related to questions of transfer.

These complex relationships entail identity development and contribute in important ways to how people may or may not be resilient in face of challenge (Nasir and Peele-Eady, 2012). As we consider cultural diversity within and across communities of practice, it is important to note that there are many cultural communities who face persistent and often inter-generational structural barriers that must be navigated and resisted in order to work toward well-being (American Psychological Association Task Force on Resilience and Strength in Black Children and Adolescents, 2008; Berry et al., 2006; Boykin, 1986; Grande et al., 2015; Lee, 2017). These possibilities of resilience in the face of challenge, indeed in the face of trauma, are extremely important to understand. In education and other fields, there has been a tendency to either assume only victimhood in marginalized communities, to assume that only through internalization of what are presumed to be mainstream cultural practices can persons from marginalized communities achieve and be resilient in the face of structural challenges and barriers. In many ways, these assumptions of hierarchies of cultural practices mirror the same assumptions of social and cultural hierarchies discussed earlier around some of the same minoritized communities. It is important to also recognize that such othering has also historically been ascribed to women as a gender.

Included here are two theoretical frameworks that embody these complex propositions about resilience in light of diversity and of the dialogic relations among physiological and psychological processes.

The first is the Phenomenological Variant of Ecological Systems Theory (PVEST) developed by Margaret Beale Spencer (Spencer, 2006; Margaret Beale Spencer, 2019; Spencer et al., 2006). Supported by several decades of empirical research, PVEST identifies a set of processes and relationships that contribute to developmental processes. PVEST is a consequential tool for theorizing about diverse pathways of learning and development across cultural communities because it articulates both foundational human processes of meaning making but requires examination of the specific sets of cultural practices taken up in these processes. Fig. 1 below captures the PVEST model. The first component asks us to identify net vulnerability. Net vulnerability is not simply what we think of as the objective reality of an individual or a group's lived experience. Rather net vulnerability is the relationship between risks faced and protective factors available. For example, poverty is not an undifferentiated risk. In countries that have societal protective factors (e.g., free health care, free pre-school, supports for housing, universal access to healthy food, enriched education for all), the experience of poverty is different from countries that do not provide these societal supports. In the same vein, growing up in a single parent household does not hold the same risks as growing up in a single parent household that includes inter-generational family and deep social networks that include friends, church, etc. Net stress refers to how the individual experiences that net vulnerability. How one experiences exposure to vulnerability depends on relationships between the nature of the challenges experienced and the supports available. Sometimes supports are available, but are not perceived by the person or the community as actually relevant or useful. This second component of the model is important because it pushes against the idea that everyone exposed to vulnerabilities will experience them the same way. This component stresses the importance of perceptions to experience. The third component is reactive coping processes. One important underlying proposition here is that to be human is to be vulnerable. To be human is to face risks. It is not simply the risks we face, but equally important the resources that are available to us to wrestle with those risks, which influence how we cope, how we make sense of such risks. Such coping, Spencer (2006) argues, may be adaptive or maladaptive. It is important to note that these coping responses are malleable, and malleable across the

Fig. 1 PVEST. Source: [Spencer \(2006\)](#).

life course. These coping processes that we learn over time become internalized as what she calls emergent identities. Emergent is important for several reasons. One is because such identities are malleable. There is no point in the life course when we are incapable of seeing ourselves differently. The fifth component is what she calls stage-specific coping outcomes that can be productive or unproductive. Stage specific takes into account how identity processes and life course outcomes shift from early childhood through middle childhood through adolescence into adulthood, and indeed include the stages of adulthood.

PVEST is offered here as a framework that supports how we can think about both homogeneity and heterogeneity within cultural communities, about both groups and individuals within groups.

The second framework is the R.I.S.E. principles. This framework evolved from the syntheses of studies of the role of culture in human learning and development, captured in the handbook by [Nasir et al. \(2020\)](#). Drawing from research in the neurosciences, cognitive and social psychology, the learning sciences, and human development, these principles capture the foundational conception of human learning and development as outgrowths of complex dynamic systems that include the following: physiological processes rooted in our evolution as a species as these physiological processes are taken up in culturally organized processes; processes that develop and unfold over time across the life course; whose intersections unfold and are embodied in social interactions, which in tandem entail and influence identity, cognition and emotions. This is indeed a complicated space whose complexity has and continues to pose challenges to how we interrogate human learning and development.

- (1) Rooted in evolutionary, biological, and neurological systems,
- (2) Integrated with other developmental processes—emotion, identity, cognition,
- (3) Shaped in culturally organized practices across people's lives,
- (4) Experienced as embodied and coordinated through social interaction

At the same time, we ignore the dynamic relations among these processes at our peril. They exist and are at work whether or not we have the tools to study them. At the same time, the evidence of individuals and communities who persist, resist, and are resilient in the face of challenge and trauma is real life evidence that these complex processes are at work; and that people in everyday settings intuitively understand them. Families understand the importance of food and rest for healthy development, the importance of loving relationships where we seek to make children feel loved and safe, value routine, often inter-generational practices for

socializing children; and as children become adolescents and adults, parents come to learn how these supports must be adaptive over the life course. We also know there are families who are middle-class and belong to communities presumed by the broader society as privileged because of ascriptions of whiteness who also experience trauma without adequate social and emotional supports to be resilient. Spencer, drawing on [Anthony \(1987\)](#), argues that there are people in privileged communities who are deeply vulnerable specifically because they have not learned to wrestle with challenge as well as people in minoritized communities and communities living in persistent inter-generational poverty who have learned to be resilient specifically because of the supports they have for wrestling with adversity. Cultural communities are both homogeneous and heterogeneous.

Because these principles are central to understanding human functioning, having been validated by decades of research converging across multiple disciplines—cognitive and social psychology, the neurosciences, human development, and learning sciences—they provide useful lenses for examinations of how these foundational principles unfold along diverse pathways, serving diverse functions within and across diverse cultural communities. We understand that diversity among cultural communities not only exists but is essential for the adaptability of our species to survive in light of challenge and changing circumstances. The warrants that undergird this body of scientific research stand in stark contrast to the earlier periods of research on human differences, such as traditions of scientific racism, eugenics, and more recent propositions about a culture of poverty.

Studies of differences in pathways of learning and development across cultural communities of practice

Two major 20th century figures influencing our understanding of human learning are Piaget and Vygotsky ([Pass, 2004](#)). [Piaget \(1952, 1975\)](#) focused on cognitive development of children across multiple stages as outgrowths of biological maturation and processes and exploration of the physical and social world around them. Rather than focusing on discrete knowledge, Piaget was concerned with the development of underlying mental structures or schemas for logical reasoning. Piaget documented these stages of cognitive development largely through experiments with European children. While Piaget attended to children's interaction with their environments, he still largely focused on cognitive development as internal processes within individuals and presumed universal stages of development. During the same period of Piaget's early research, Lev Vygotsky in Russia was studying children's development. While these two are often pitted against one another, they actually did correspond and connect to one another's work ([Pass, 2007](#)). [Vygotsky \(1978, 1981, 1977\)](#) argued for the centrality of social interactions as the medium of development, with social interactions as the way children learn to intuit cultural norms and practices. This proposition means that developmental processes are not universal but vary by virtue of diversity in the range of cultural practices into which children are socialized. Rather than stages of development as Piaget proposed, Vygotsky identified what he called the zone of proximal development or the ZPD. Rather than learning as an outgrowth only of the individual child's exploration, Vygotsky argued the usefulness of focusing on what children are able to learn as tasks just beyond what they can do on their own, scaffolded by the support of more knowledgeable others, along with the possibilities that different cultural artifacts make available to the learner. Such cultural artifacts include language. [Cole \(1996\)](#), drawing on earlier work by [Warkofsky \(1973\)](#), identifies different categories of cultural artifacts: primary artifacts (used directly in acts of production), secondary artifacts (representations of primary artifacts and modes of action, such as recipes and beliefs), and tertiary artifacts (examples include imaginary worlds such as works of art). These artifacts are cultural in that they are created by human beings working in coordination with one another for the purposes of carrying out socially constructed tasks. This brief history is offered because these two bodies of research influenced a powerful family of research on cultural foundations of learning across different cultural communities.

By the 1970s, a number of cognitive psychologists (Michael Cole, Vera John-Steiner, James Wertsch) discovered Vygotsky and translated much of his seminar publications into English. A number of these psychologists decided to test the idea of universal stages of logical reasoning by examining how communities of practice within different cultural communities outside of Europe engaged in logical reasoning, including looking at adults and children. They were faced with the challenge of disentangling the role of formal schooling and interrogating the assumptions that informed the instruments being used to measure logical reasoning. Interesting, as a result of these cross-cultural studies, [Piaget \(1966/1974\)](#) began to think differently about his final stage of formal logical reasoning. These cross-cultural studies often found that non-schooled populations would classify not on the basis of taxonomic categories but rather on the basis of functionality. On tasks of syllogistic reasoning, some studies, such as [Luria's \(1928\)](#) interviews with rural non-schooled and schooled Tadzhikistan and Uzbekistan populations in Central Asia found that non-schooled people did not accept the fundamental assumptions identified in the syllogistic task, but rather responded that the reasoning depended on the circumstances. Circumstances often involved first-hand knowledge as the criteria for truth rather than an abstract de-contextualized claim. In cross cultural studies of memory, researchers found that how objects subject to recall were situated in culturally familiar contexts mattered. As [Rogoff and Chavajay \(1995\)](#) note:

The conclusion from the memory studies, as with the classification and logic studies, is that researchers cannot just assume, as we did before cross-cultural research, that a cognitive test reveals a general ability across tasks unrelated to people's experience ... It is a very simple conclusion but one that transformed how researchers think about the generality of cognitive tests and about their relation to people's experience with particular institutions such as schooling (p. 863).

Rogoff and Chavajay offer a comprehensive overview of these foundational studies. [Scribner and Cole \(1981\)](#) studied how differences in literate practices among the Vai people of Liberia supported different skills, concluding that literate skills were not simply generic. Vai literacy included their indigenous phonemic-syllabic language, Arabic learned as part of Islam, and English learned in school. Each contributed to different literate skill sets. Another body of research documented the learning of arithmetic operations through the practices of tailoring and merchant activities in countries in Africa and South America ([Carraher et al., 1985](#); [Lave, 1977](#); [Nunes et al., 1993](#)). As opposed to general strategies, they studied differences in strategies for arithmetic problem solving associated with the routine everyday practices rather than simply invoking canonical strategies associated with schooling ([Lave, 1988](#)). In the studies of developing and using everyday numeric reasoning strategies, researchers were able to show how social relationships, scaffolded supports from others and artifacts structured problem solving, rather than viewing such reasoning as solely a process of internalization by individuals. For example, [Saxe \(1988a,b\)](#) studied children in Brazil who were poor, often unschooled, who sold candy on the streets of an urban city. He documents how these children are able to mentally calculate sums and cash due back as they sold packets of candy, largely to foreigners; buy candy in bulk and determine the best pricing per unit for re-sale, influenced in part by daily differences in the rate of exchange for foreign currency. He carefully compares the calculation strategies these candy sellers learn on the streets with the calculation strategies taught in schools, also showing how these children were more efficient in calculating in problems that mirror the tasks they tackle in selling on the streets. Another important dimension of Saxe's studies here was his documentation of the social processes and interactions through which children developed different levels of expertise in the practice. These included older children who were more experienced as candy sellers scaffolding the efforts of younger children, along with supports by merchants from whom they purchased candy in bulk. This was a unique example of scaffolding among children.

These studies together support the idea that displays of competence are not universal. Some competencies that have characterized measures of intelligence have presumed that tasks associated with formal western schooling capture undifferentiated universal indicators of ability. However, decades of cross-cultural studies of performance have shown how skill in performance is associated with participation in routine cultural practices which do not have to be limited to the practices of schooling. These performances around memory, classification, literacy and numeracy clearly are functional in that people in particular communities are able to carry out consequential tasks using culturally specific skills.

Another interesting dimension of these cross-cultural studies has been differences in community based shared assumptions about what it means to be intelligent, what it means to be skilled. These cultural values help to shape people's identities in terms of goals to pursue. For example, [Marcus and Kitayama \(1991\)](#) have demonstrated differences in perceptions of the self among Pan Asian communities and European descent communities. Asian communities tend to value the idea of an inter-dependent self where relationships with others are privileged. At the same time, they document that these community values are not necessarily held by every individual in the community. In a similar vein, earlier studies among ethnic communities in Africa document a similar valuing of inter-dependence—responsibilities to family and elders, of social obligation ([Beattie, 1980](#); [Diop, 1978](#); [Serpell, 1974, 1982](#); [Super and Harkness, 1986](#)). Other studies have shown how this valuing of inter-dependence can play out in formal schooling where the valued forms of social interaction privilege independence. [Philips \(1983\)](#) has shown how children from indigenous communities in the US may be reticent in drawing attention to themselves in classrooms that value competition. [Boykin \(1997\)](#) has shown how many African-American children prefer learning experiences that are collaborative versus ones that based on individual competition, and experiences that embody physical verve. [Rogoff et al. \(1995, 2014\)](#) have shown how children from indigenous communities of the Americas learn by intent participation. Here, as opposed to age-based segregation, children are incorporated into routine productivity activities of the family and learn by observing and participating.

One of the most informative studies to capture the breadth of complexity entailed in how people learn and the crucial role of participation in cultural practices within and across time is Saxe's ([Saxe and Esmonde, 2005](#)) longitudinal study of mathematical everyday reasoning among Oksapmin of Papua New Guinea. The Oksapmin historically developed a system for counting using a system of 27 body parts. Originally, saying Fu with a raised fist meant that all 27 body parts have been counted. However, in later years Fu came to mean double the last body part identified. Saxe showed how the meaning of Fu shifted over historical periods, influenced in part by the system of economic exchange involving cash exchanges using pounds and shillings brought by western colonial powers, and then shifts by the Australian government to dollars and cents, and the eventual independence of Papua New Guinea with currency in kina and toea, all requiring abilities to calculate amounts greater than the body counting system supported. That, in conjunction with bringing in western schooling, introduced school-based strategies for counting. Saxe developed a series of tasks asking people of different ages to explain the meaning of Fu. He found differences in the understanding of Fu and its shifting meaning based on age cohorts—elders, unschooled adults, schooled adults, schooled adolescents, and children. The goal was to identify persons who experienced both the shift in forms of economic exchange, some formal schooling but earlier training in the traditional methods, and young children who experienced only western formal schooling. That longitudinal study shows the functional role of cultural artifacts (Fu as a traditional construct, systems of economic exchange based on shifts in currency) in helping to shape how people reason, and how such influences are historically situated and taken up in specific cultural practices.

There are more recent cross-cultural studies that have introduced an important idea, namely, to reconsider the ontologies of the academic disciplines that have presumed to have been the primary purview of formal schooling and European and Euro-American intellectual traditions and practices. In some cases they offer fundamentally different epistemological dimensions to the knowledge domain, as in the work on indigenous knowledge systems in reasoning about the natural world by Bang and colleagues ([Bang and Marin, 2015](#); [Bang et al., 2013](#); [Bang and Medin, 2010](#)). Bang argues that indigenous knowledge systems do not position humans at the top of a hierarchical ladder. Rather they privilege the inter-dependence across all elements of the natural world. She further

argues that despite formal western schooling privileging humans at the top of a natural order, more recent basic research in the sciences reflects an understanding of our inter-dependence (Chief et al., 2018; Kimmerer, 2013; Makondo and Thomas, 2018). In other cases, studies document how foundational concepts and reasoning processes are embedded in everyday cultural practices that are not directly connected to or typically taken up in schooling. These include Lee's (1995, 2001, 2007) work in Cultural Modeling on sensemaking around narrative and figuration in everyday language practices among speakers of African American English, in hip hop and other popular music genres; Taylor's (2009, 2012) work documenting the mathematical reasoning around number sense among young children outside of schooling; Brown's (Brown, 2004; Brown and Kloser, 2006; Brown and Kelly, 2007; Brown and Kloser, 2009) research documenting the intuitive understandings of physics among school aged baseball pitchers; Nasir (2000, 2002, 2005) research on mathematical reasoning of children learning to play dominoes and high school basketball players; Major's (2001, 2003, 2015) research on narrative sensemaking and moral reasoning in what she calls Shop Talk in African-American beauty salons; Fisher-Winn's (Fisher, 2003, 2005, 2007; Winn, 2010) research on literacy learning, particularly around narrative and figuration in African-American community based arts institutions and sites of incarceration; Emdin's (2010a,b) work connecting hip hop and science learning (Orellana, 2009; Orellana et al., 2003; Orellana, 2001; Valdes, 1996, 2001, 2002; de los Ríos, 2019; de los Ríos and Molina, 2020; de Los Ríos and Seltzer, 2017) research examining the meta-linguistic knowledge embedded in culturally rooted and translanguaging practices among young people who are English Language learners (using structural knowledge of the first language to inform comprehension processes in the second language; translating issues of point of view and positioning from English into the home language for family members); Gutierrez's (Gutierrez, 2014; Gutiérrez and Jurow, 2016; Gutiérrez et al., 2009) design research with children from migrant communities in California using cultural practices around story telling (testimonios) as tools for creating external representations of their critical social and political analyses of ideologies and structures that create barriers for their communities.

The point is that all of these studies are centered in what young people learn through socialization in community specific cultural practices outside of formal schooling, and where the researchers are able to document the underlying epistemological and logical relationships between these community-based practices and those within the disciplines of literary analyses, science, and mathematics as formally represented in the traditions of formal schooling. Equally important, these bodies of research include how these settings of everyday learning in cultural contexts entail attention to social relationships among actors, position novices as efficacious, create spaces in which learners feel safe and perceive what they are learning as relevant, and engage with culturally specific artifacts. In other words, learning in these diverse everyday settings captures the complexity of the underlying principles of human learning and development discussed in the opening sections of this chapter. The underlying principles are universal. However, their enactment and embodiment differ by virtue of differences in routine cultural practices and the differences in culturally informed purposes such practices are intended to support.

Introduction

Indigenous perspectives of identity development stress that identity formation is situational, and impacted by one's sense of belonging to a collective and connectedness to other factors in the context, including people, places, and spaces (McIntosh, 2006; Webber, 2015). In this chapter we argue that Indigenous student academic identities are developed, experienced, and expressed in unique ways by Indigenous students. Drawing from Social Identity Theory, Stereotype Threat, and Indigenous Social-Psychological Theory this chapter explains how schools can create environments that enable Indigenous students to succeed alongside other students. Social Identity Theory (SIT) (Tajfel, 1981) posits that a student's sense of who they are is highly influenced by their group membership(s) and student motivation at school relates to whether those groups are negatively or positively represented in society more broadly. This links to what Steele (1997, 2010; Steele and Aronson, 1995) and others refer to as "stereotype threat" where generalized societal perceptions (stereotypes) of social groups manifest as a social-psychological threat that can hinder a negatively stereotyped student's performance and engagement at school. Both SIT and Stereotype Threat are explored in this chapter, along with their influence on the engagement of Indigenous students in schooling contexts.

Indigenous social-psychological theory suggests that in order for Indigenous students to succeed in education, more attention must be paid to their identities, particularly their ethnic and cultural identities and what this means for them, their whānau and wider communities (González et al., 2022; Houkamau and Sibley, 2015; Webber and Macfarlane, 2020). This perspective is framed within research that argues for a holistic and culturally rich approach to teaching and learning. The Mana Model presented in the second half of this chapter, developed from an Indigenous Māori worldview, provides a framework for understanding the important conditions that Indigenous students need to succeed and thrive at school. These conditions include connectedness to others and collective agency (mana whānau); belonging and relationship to place (mana ūkaipō); embedded achievement and self-concept (mana motuhake); social psychological competence (mana tū); and a diverse knowledge base and skill set (mana tangatarua). The Mana Model suggests that Indigenous student thinking, behavior and mental wellbeing is motivated by the desire to achieve a sense of mana—self-efficacy, purpose, pride and belonging. This chapter argues that when schools focus on these five conditions for mana development for all students, they are able to learn in a way that supports their wellbeing, academic persistence, and confidence. The Mana model, drawn from Indigenous social psychology, is underpinned by the belief that all students possess valuable knowledge, skills, and attributes that they can utilize to succeed at school and contribute positively to the world around them.

Social identity theory

Social identity theory (SIT) is a theory that explores intergroup relations and social identity. The work of Tajfel (1969, 1974, 1978, 1981; Tajfel et al., 1971) and his graduate student Turner (Tajfel and Turner, 1979; Turner, 1975) added a valuable social dimension to social psychology, which predominantly focused on individual and inter-individual processes at the time. Tajfel (1972) defined social identity as an "individual's knowledge that he belongs to certain social groups together with some emotional and value

significance to him of this group membership" (p. 272). SIT was predicated on the idea that the wider social context, and an individual's social identities, are significant factors in intergroup behavior and self-concepts. SIT seeks to understand how one's social identity is constructed, internalized and expressed.

A key element of this process involves social categorization, a process whereby individuals categorize both themselves and others into groups. Factors that might influence categorizations include ethnicity, age, and gender as well as occupation and socioeconomic status. [Tajfel and Turner \(1979\)](#) proposed that social categorizations are a way to organize and stratify social contexts and help individuals to define and place oneself within social settings. Additionally, being a member of a social group comes with ingroup defining expectations of how to think and act. [Tajfel \(1981\)](#) states,

in an infinite variety of situations throughout his life, an individual feels, thinks and behaves in terms of his social identity created by the various groups of which he is a member and in terms of his relation to the social identity of others, as individuals or *en masse*.

[Tajfel \(1981, p. 31, emphasis in original\).](#)

[Turner \(1987\)](#) and colleagues ([Onorato and Turner, 2004](#); [Turner and Reynolds, 2012](#)) later clarified the categorization process as Social Categorization Theory (SCT). SCT posits self-concept as situational, in that all social contexts compel individuals to either emphasize or de-emphasize particular social identities in order to construct a salient "ingroup" identity relevant to the context ([Onorato and Turner, 2004](#); [Turner and Reynolds, 2012](#)). This ingroup identification consequently influences an individual's thinking and behavior in that space ([Turner and Reynolds, 2012](#)).

SIT proposes that individuals are motivated by a desire for a positive self-esteem and that this drives group membership. A central idea within SIT is that individuals are inherently motivated to achieve a positive sense of social identity ([Tajfel, 1974](#); [Tajfel and Turner, 1979](#)). A positive sense of social identity develops when an individual belongs to certain social group(s) that are distinguishable and invoke a feeling of positive membership ([Tajfel, 1978](#)). Based on a large and continual body of research SIT posits that group categorization, coupled with the desire for a positive social identity, is an explanation for intergroup conflict, discrimination, and prejudice ([Hogg, 2016](#); [Turner, 1975](#)) and the prevalence and reproduction of unequal group power relations in society ([Abrams and Hogg, 2010](#)). [Hogg \(2000\)](#) also argues that social identity is motivated by the human desire for subjective certainty—understanding how to think and feel, knowing how to behave and what to expect in different situations and relationships. This argument posits that individuals are motivated to self-categorize with a clear and distinct group in order to alleviate identity uncertainty and view and understand the self in comparison to others ([Abrams and Hogg, 2010](#); [Hogg, 2000](#)).

The stereotypes associated with one's social group can impact whether membership in that group contributes positively or negatively to an individual's social identity and self-esteem. [Tajfel \(1969\)](#) theorized that stereotypes are assigned to social groups to create clear distinctions between groups, and that they are culturally specific and evolve throughout history ([Tajfel, 1969](#)). [Tajfel \(1969\)](#) stated:

through personal and cultural experience, dimensions such as "intelligent," "lazy," or "honest" are subjectively associated with classifications of people into groups. As long as we have little specific knowledge about an individual, we shall tend to ascribe to him the characteristics which we derive from our knowledge of his class membership, be it a class of trade unionists, undergraduates, animal lovers, or Patagonians (p. 178).

He goes on to say that at both an individual and group level, once these stereotypes are assigned, finding evidence to support the stereotype is far easier than noticing their contradictions. Stereotypes contribute to the overall social perception of a group, influencing the status of different groups and the positive or negative influence being a member of a group has on an individual's self-perception. For Indigenous students the stereotypes associated with their social group can be negative given they are often ascribed by the dominant group that, as posited by SIT, is motivated to maintain their own positive self-identity by negatively stereotyping others.

SIT main influences for Indigenous students

In educational contexts, stereotypes and in-group and out-group categorizations can impact Indigenous students' academic motivation and engagement. It does so by disrupting the identity-motivation process and influencing the parameters within which they can imagine their possible selves and any strategies needed to attain success. [Oyserman \(2007\)](#) has asserted that motivation is fueled by a desire to (a) progress from a current-self state to a future-self goal (or possible self), and (b) away from possible negative selves. [Oyserman \(2007\)](#) argued that this is a culturally located process as culture influences desirable goals, behaviors, and strategies to succeed. Furthermore, research has shown that behaviors conducive to academic achievement (such as studying and in-class questioning) have become infused with the dominant group due to the association between success at school and success and power in wider society ([Oyserman, 2007](#); [Ogbu, 2004](#); [Burnaford, 2015](#)). The educational behaviors accepted in wider society may not align with Indigenous student's social identities (including racial-ethnic identity, gender and class-based identities), reducing the

likelihood that Indigenous students will be motivated to participate fully in these behaviors (Oyserman and Lewis, 2017). Certain behaviors are associated with what “people like me” do and when these identities are salient it inspires group-defining behavior, that is education engagement or dis-engagement (Burnaford, 2015; Oyserman, 2007; Oyserman et al., 1995; Oyserman and Lewis, 2017).

Indigenous students face additional challenges as they may be less likely to imagine their possible academic selves (defined by the education system) while still remaining central members of their social groups (Burnaford, 2015). This is because an Indigenous student’s academic self may conflict with their social identity, particularly if their social identity has been constructed in opposition to the dominant group (Fordham and Ogbu, 1986). An individual can have multiple social identities and when they are not compatible, certain social identities may dominate and “override” others (Oyserman, 2007). Verkuyten et al. (2019) argued that ethnic-racial discrimination (stereotypes and prejudice based on ethnic or racial group) threatens core components of identity (belonging, esteem and control). These authors have proposed that when identity is threatened students can respond with increased or decreased academic engagement.

Indigenous students who are aware of negative societal attitudes toward their group (such as being stereotyped as low achievers) may attempt to “leave” or distance themselves from their social group or categorizations, and join or be accepted by another group through certain behaviors such as academic engagement (Tajfel and Turner, 1979). This “strategy of racelessness” (Fordham, 1988, p. 54) means that Indigenous students feel as though they must distance from their social groups in order to succeed in an individualistic education system. For many Indigenous students this strategy is difficult because (a) physical features may render groups impermeable (Abrams and Hogg, 2010) and (b) disconnecting from one’s ethnic or cultural group and engaging in out-group behaviors may result in discrimination from in-group members (Fordham and Ogbu, 1986; Ogbu, 2004; Carter, 2006). In essence, Indigenous students who experience negative stereotypes and/or self-concept in educational contexts, or who feel as though their identities are not congruent with academic behaviors and success (Oyserman and Lewis, 2017), are more likely to withdraw from school in search of a different positive social identity (Abraham, 1989; Kelly, 2007; Tajfel and Turner, 1979; Webber, 2015). Constructing a group identity with oppositional references and behaviors to the dominant group is a minority identity protective factor (Fordham and Ogbu’s, 1986). Within educational contexts, the temporary reprieve from one’s negative social identity and its influences on self-esteem has long term consequences for Indigenous students’ futures and contributes to the perpetuation of underachievement for certain groups.

Stereotype threat

Despite many Indigenous students and their families valuing education and having high academic aspirations for themselves or their children (Carter, 2006; Graham et al., 2010; Macfarlane et al., 2014; Mello, 2009; Rudolphi and Salikutluk, 2021; Webber and Macfarlane, 2020) there remains an inconsistency between Indigenous educational aspirations and academic outcomes. Identity motivation theory posits that many students envisage academic possible selves, the issue is whether these possible future identities are salient and connected to effective strategies and help students persevere through difficulty (Oyserman and Lewis, 2017). Stereotype threat is helpful to understand how stereotypes about one’s identity may disrupt this process and be an obstacle for Indigenous students learning and motivation. Steele and Aronson (1995) first coined the term stereotype threat, defining it as “being at risk of confirming, as self-characteristic, a negative stereotype about one’s group” (p. 797) “both to one’s self and to others who know the stereotype” (p. 807). Steele (2010) stated that “stereotype threat is a standard predicament of life” (p. 5) because humans are critically aware of each other, we know how our identities correlate to stereotypical ideas, including the assumptions surrounding gender, age, wealth and ethnicity. Thus, when Indigenous students are presented with a situation at school in which they might be judged because of who they are or are at risk of confirming existing stereotypes about element(s) of their identity, there is a social-psychological threat at play which can hinder their performance (Steele, 1997). Appel and Kronberger (2012) also add that stereotype threat can hinder individuals “from building knowledge and abilities in the first place” (p. 630), making stereotype threat a key issue in education.

Stereotype threat and Indigenous students

The achievement gap between Indigenous and other ethnic minority students and their dominant (often White) peers is evident globally, for instance: Black and Hispanic students in the United States (De Brey et al., 2019); students from Black backgrounds in England (Hutchingson et al., 2020); and Indigenous and Aboriginal students in Australia (Fahey, 2021). In Aotearoa New Zealand, while there have been considerable improvements in the past 10 years, the academic achievement gap between Māori and Pacific students and their European peers persists (NZQA, 2020). Despite achievement gaps being influenced by a myriad of socioeconomic factors (Reardon et al., 2019), as well as being influenced by the values within the education system itself (Webber, 2012), many subgroups are stereotyped as groups that will underachieve “in certain cognitive tasks” (Appel and Kronberger, 2012, p. 610). Persistent stereotypes within the education system in Aotearoa New Zealand frame Māori and Pacific students in deficit ways and make assumptions about the families and home lives of these students to explain underachievement (Turner et al., 2015).

Stereotyped students are aware of societal assumptions about their group. Webber et al. (2013) study found that Māori students were able to clearly identify academic stereotypes related to Māori, including “the perceived notion that Māori are ‘not very smart’, ‘dumb’ and ‘drop out’” (p. 50). When Indigenous students encounter spaces where they feel their stereotypes are highlighted, academic achievement and engagement can be negatively impacted (Webber and Macfarlane, 2020). Steele and Aronson (1995) demonstrated that African American students noticeably underperformed their White peers when they sat test under conditions that elevated “negative stereotypes about their group’s intellectual ability” (p. 807). They showed that when students were told that their scores were indicative of their intellectual ability or were asked to record their ethnicity, stereotype threat was heightened to the detriment of the outcomes in the test. Conversely, when conditions alleviated stereotype threat (i.e., tests were not presented as being diagnostic of ability or did not ask students to record their ethnicity) African American students performed to the same standard as White students. This demonstrates that stereotype threat has a marked impact on test performance and can result in an achievement gap between negatively stereotyped students and those who are not. As well as ethnic minority groups, research has illustrated the impact of stereotype threat on the cognitive performance of physically disabled students (Desombre et al., 2018) and girls’ and women’s achievement and engagement in mathematics (Steele, 1997; Good et al., 2008), highlighting how stereotype threat can affect many different groups in an array of contexts where stereotypes apply.

Stereotype threat impacts the personal, social and institutional lives of Indigenous students, creating an added obstacle to personal thriving. A further consequence of stereotype threat is that Indigenous students may feel they must compromise or minimize elements of themselves (Webber and Macfarlane, 2020) or redirect their education because of the threat that existing stereotypes have for their self-esteem and identities (Steele, 1997). Steele (1997) speaks to the difficulty of stereotype threat, pointing out that the more students are invested in a particular domain, and the greater influence this domain has on their identity, the higher their risk of stereotype threat. Thus, stereotype threat predominantly impacts Indigenous students that have both the interest and skills to achieve at school. The risk is that these students will disengage from domains where they feel stereotyped, tragically impacting the “academic identities and performance outcomes of large segments of society” (Steele, 1997, 614). An example of this is the disproportionate number of Indigenous scientists (McAllister, 2022) and academics working in universities (McAllister et al., 2019). In essence, Indigenous students are more likely to disidentify and disengage from domains in which they experience a threat and remove the influence these domains have on their identities (Good et al., 2007).

This perspective on the obstacles facing stereotyped students places emphasis on social-cultural change, deeming that school environments (including teacher expectations) and implicit and explicit messaging within these environments are crucial factors that can help and hinder student engagement and achievement. Steele (1997) offers the hopeful perspective that alleviating stereotype threat in education settings will reduce its impact on student decision making and achievement.

Indigenous social-psychological theories

Māori, the Indigenous people (tangata whenua) of Aotearoa understand identity formation as a process underpinned by the concepts *mana* and *mauri*. Mana is defined as honor, pride and esteem (Royal, 2006). Mana has a both an individual and social component. It involves an individual’s sense of self, and the degree in which they feel confident, empowered, and well. Mana is also attributed to an individual through the perceptions others have of them based on their contributions to their communities, and the ways they positively impact the lives of others around them (Royal, 2006; Dell, 2017). Royal (2006) explains that due to colonization Māori have experienced painful forced separation from their land and disenfranchisement throughout history that has resulted in a collective dulling of mana Māori. Thus, he argues, mana restoration must occur at an individual and collective level. For individuals, this process is heterogeneous with some developing their Māori identity through connection with Māori communities (iwi, hapu), Māori knowledge, history and whakapapa (genealogy), whereas for others this process may involve fulfilling relationships with non-Māori.

This process of developing mana is linked to another key Māori concept called “mauri” (Royal, 2006). Mauri is a spiritual “active force of life” (Mead, 2006, p. 83) that empowers the body, mind and spirit of all individuals. According to a Māori worldview, mauri is infused within all living beings, including the natural environment (land, trees, water, and animals) and people. Durie (2001) explains that mauri flows between these elements mediating their relationship and continuing their mauri force. The intrinsic mauri force energizes the pursuit of mana as well as the journey to belonging, wellbeing, and a sense of purpose. These concepts are central to Māori identity construction and align with theories of becoming.

From an Indigenous perspective, identity is forged through a negotiation between past, present, and future. For Indigenous populations this positioning is defined and shaped, to varying degrees, by colonization (McInerney and Flowerday, 2016). Thus, identity construction for many Indigenous populations is influenced by the struggle to survive as a minority ethnic group in their own lands, often subjected to marginalization and direct attempts at assimilation (Alfred and Cornthassel, 2005). McIntosh (2006) explored the complexity of Māori identity, considering the “fixed,” “fluid,” and “forced” ways in which contemporary Māori identities are constructed. While she states that “Māori identity is a marginal identity in Aotearoa/New Zealand” (p. 70, emphasis in original) she argues that marginality is expressed in many forms and that there is no universal process of Māori identity construction nor homogenous Māori identity.

Firstly, Māori identity can be constructed through traditional characteristics. “Traditional” indicators of Māori identity such as kin, Māori community, cultural participation, knowledge of whakapapa and Māori history, and use of te reo Māori are examples of characteristics from a Māori ecology (Moeke-Pickering, 1996) also referred to as “primordial” constructs of Māori identity (Webber, 2007). Whakapapa—the layering of generations, tribal stories and traditions that link Māori to the past and to each other (Connor, 2019; Te Rito, 2007), is “generally agreed to be the key characteristic” of Māori identity (Webber, 2012, p. 22). Te Rito (2007) writes, “[h]aving knowledge of whakapapa helps ground us to the earth. We have a sense of belonging here, a sense of purpose, a *raison d’être* which extends beyond the sense of merely existing on this planet” (p. 4). Traditional Māori informed ideas about what constitutes a Māori identity is important to assert positive Māori-centric perspectives and progress political activism (Hoskins, 2012; McIntosh, 2006). However, the classification of Māori identity according to “fixed” characteristics (Metge, 1964; Ritchie, 1963) have been criticized for being exclusory, overly simplistic, and restrictive (McIntosh, 2006; Walker, 1989). Durie (1995) argued that these traditional characteristics of Māori ethnic identity will be of varying importance to modern Māori, and do not influence any individual’s status as Māori.

Māori scholars have also argued that Māori identity construction is contextually influenced (Durie, 1995; Webber, 2007; Houkamau, 2011). Kukutai (2004) points out that defining Indigenous populations across the world for policy purposes is difficult, given the variety of expressions of Indigenous identity and the diverse lifestyles, social economic status, experiences, and attitudes within Indigenous communities. “Fluid” Indigenous identities emerge in response to context and are generally inclusive of diverse expressions of Māori identity. As McIntosh (2006) stated “[t]he fluid identity ‘plays’ with cultural markers such as language, custom, and place and reconfigures them in a way that gives both voice and currency to their social environment” (p. 83). The current political and social climate, socio-economic status, lifestyle choices and experiences influence what being Māori looks and feels like at an individual and group level. Factors such as land alienation and political struggle for resources have impacted Māori identity and potentially restricted access to some primordial characteristics (Moeke-Pickering, 1996; Greaves, 2017). Thus, this form of identity construction establishes Māori “roots” in the diverse lives of Māori people, establishing community and culture in more flexible ways.

Lastly, McIntosh (2006) speaks to “forced” identity construction whereby outsider group perceptions dominate identity formation. In the case of Māori, forced identities are shaped by the lack of agency Māori have to define themselves and further constrained by the reality of disadvantage that many Māori experience. Māori experience much higher rates of racial discrimination than Pākehā (Cormack et al., 2018), have lower educational attainment (Ministry of Education, 2020a,b,c), suffer poorer health outcomes (Ministry of Health, 2019; Statistics NZ, 2021), including mental health (Fleming et al., 2020; Paterson et al., 2018), child poverty (Duncanson et al., 2021), unemployment (Ministry of Business, Innovation and Employment, 2017), and prison rates (Department of Corrections, 2021). These statistics contribute to a societal narrative about what it means to be Māori, and the reality is that many Māori inherit these negative beliefs about their own identity (McIntosh, 2006).

Evidently, Indigenous theorization of identity construction includes multiple perspectives, forms and expressions. There is no singular way to “be” Indigenous and thus instead literature explores how Indigenous identities interact with tradition, context, and with the multitude of other identities that individuals hold. Through a Māori worldview all individuals have an innate energy force (*mauri*) to pursue honor, pride, and esteem (*mana*) (Royal, 2006). This chapter asserts that educators, educational researchers, and policymakers must come to understand the integral nature of *mana* and *mauri* to fully meet the educational needs to Indigenous Māori students. They must also reflect on how they can be activated and developed in classrooms and school contexts. A focus on the development of *mana*, and the activation of *mauri*, may go some way to helping Indigenous Māori students to feel positive about their social and academic identities—while keeping their ethnic and cultural identities intact.

Māori student success and the *mana* model

Māori perspectives take a holistic view of student success recognizing that most definitions of success are often defined by the dominant group (Milne, 2009). Māori students must be seen as capable of succeeding and as having the *mauri* (energy), and *mana* (intrinsic interests and strengths) that enable them to thrive at school and in classroom environments. Durie (2011) states,

Indigenous success, often the product of resilience, has several dimensions but essentially encompasses individuals and groups, a capacity for positive engagement, and a level of autonomy. Much of the literature on resilience centres on the potential of individuals to overcome personal trauma and succeed. However, resilience is also about the achievements of collectives: families, *whānau*, communities, tribes, mobs, and whole populations. Success in that sense is a shared experience which reflects an ability to adapt and a propensity for turning adversity into accomplishment (p. 30).

The *Mana Model* (Webber and Macfarlane, 2020) is an example of an Indigenous model of student success that places emphasis on Māori student identities, effective classroom conditions for learning, enduring teacher-student-family relationships, and localized curriculum. The *Mana Model* was developed through research with successful Māori students, their *whānau*, and community to identify the personal and contextual factors that contributed to their success (Macfarlane et al., 2014). The model asserts that students are “motivated by the desire to achieve a sense of *mana*” (Webber and Macfarlane, 2020, p. 35) which lies at the heart of student identity, self-concept, and their sense of belonging. The *Mana Model* includes five *mana*-based conditions that enable

student success from an Indigenous Māori perspective: Mana Whānau (connectedness to others and collective agency), Mana Ūkaipō (belonging and relationship to place), Mana Motuhake (embedded achievement and self-concept), Mana Tū (social psychological competence), and Mana Tangatarua (diverse knowledge base and skillset).

Mana whānau—connectedness to other and collective agency

Mana whānau is an important condition for Māori student success. The word *whānau* refers to familial relationships in the Māori language. Mana whānau is derived from connectedness to others and a sense of collective agency. This dimension aligns with Indigenous research that expresses the foundational nature of whānau and close personal relationships with others for Māori identity development (Houkamau and Sibley, 2010) in both traditional and contemporary times (Moeke-Pickering, 1996). Research shows that whānau and social relationships are central to a range of Māori identities such as those of women (Houkamau, 2011), men (Rua et al., 2017), youth in South Auckland (Borell, 2005), and students (Macfarlane et al., 2014). The importance of social well-being for student self-concept, motivation, and behavior is also supported by social psychological theories. These theories state that humans have a fundamental “need-to-belong” and that self-esteem develops according to levels of belongingness and the degree to which one believes they deserve to belong (Baumeister and Leary, 1995; Leary and Baumeister, 2000; Allen et al., 2021). Elliot et al. (2004) also argue that a sense of mattering—feeling significant in their relationships with others—is important for self-concept. Thus, students benefit from reciprocal relationships where they feel they have the skills to help and uplift others. Within this, relationships where students feel connected to others (relational) and appreciated as unique individuals (autonomy) are crucial (Barber and Schleiterman, 2008). Mana whānau asserts that students have an inherent need to feel safe, valued, and important in their social networks, from this they are able to develop valuable connections with those around them and a sense of belonging to their families, school and community.

Mana whānau is fostered when whānau (including school whānau) create child-centric environments that are invested in the holistic wellbeing of students and committed to helping students succeed (Webber and Macfarlane, 2020). Having whānau at home that are engaged with students development, learning and achievements establishes connectedness and belonging (Flores-Verduzco et al., 2020). Through community-school relationships, this child-centric attitude can align with the school environment and create consistent social support in the lives of students. When students have this crucial foundation, they are able to develop fundamental social skills and a secure sense of identity. Students are then motivated to succeed and contribute positively to their social groups, be it their school, family, or community (Webber and Macfarlane, 2020).

Mana ūkaipō—belonging and relationship to place

Mana ūkaipō refers to a sense of belonging and relationship to place. The word *ūkaipō* refers to a sense of place and belonging in the Māori language. Mana ūkaipō involves being connected to the school environment and being socially connected to others within the school environment. A relationship to place develops through meaningful positive experiences in a space, experiences which create place attachment (Reih, 2020) and establish a “meaningful location” (Lewicka, 2011). This is important for student development and wellbeing (Reih, 2020). Furthermore, school belonging has been defined by Goodenow (1993) as “the extent to which students feel personally accepted, respected, included, and supported by others in the school social environment” (p. 80). Supportive relationships with peers, teachers, and parents contribute to school belonging (Allen et al., 2016). School belonging has been linked to improved mental health and wellbeing (Arslan, 2018; Allen et al., 2016; Pikulski et al., 2020) as well as academic outcomes such as achievement, engagement, and behavior (Allen et al., 2016; Blum, 2005; Furrer and Skinner, 2003; Korperschok et al., 2019). Indigenous knowledge systems develop within the unique ecology of a place and thus contain fundamental resources for learning (Barnhardt, 2005; Highfield and Webber, 2021). Harnessing the language and culture “Indigenous to a particular place is a fundamental prerequisite for the development of culturally-healthy students and communities associated with that place” (Alaska Native Knowledge Network, 1998, p. 2). From this perspective, establishing school belonging and attachment necessarily involves learning that is situated in the surrounding environment. This sentiment is shared by Place Based Education (PBE) which broadly focuses on two core questions: “what is this place?” and “what is our relationship with it?” (Penitito, 2009). The intention of PBE is to learn *through* culture as opposed to *about* culture; PBE provides a lens in which to do so and combines Indigenous and Western perspectives to the benefit of all students (Penitito, 2009; Webber and Macfarlane, 2018).

Learning through (Indigenous) culture, language, and history fosters mana ūkaipō (Webber and Macfarlane, 2020) and strengthens Māori students’ academic and social identities. This is a view shared by culturally sustaining schooling—also referred to as culturally relevant pedagogy and culturally responsive teaching (Highfield and Webber, 2021). Researchers in this field argue that a mismatch between student’s home lives and school contributes to the achievement gap, and that creating a synergy between home and school culture can benefit students’ learning and engagement (particularly Indigenous students) (Castagno and Brayboy, 2008). Webber and Macfarlane (2018) show how education centered around iwi (tribal) knowledge and genealogy can support Māori success, achievement, and cultural identity as Māori historical icons demonstrate important cultural values and inspire motivation and commitment to success. Importantly, Indigenous and cultural knowledge is held by the communities themselves

requiring that schools establish genuine and reciprocal relationships with their wider communities (Webber and Macfarlane, 2018). It is through these relationships and the meaningful incorporation of cultural knowledge that student's cultural identities are recognized, fostering a sense of connection and belonging.

Mana motuhake—embedded achievement and self concept

Mana motuhake develops when students have a positive sense of identity and self-concept as this is central to learning and wellbeing. The Māori word *motuhake* refers to a person's distinctiveness, self-concept, or sense of personal authority in the Māori language. Self-concept is the thoughts and feelings one holds about oneself (Rosenberg, 1979) that are derived from past experiences, the perceptions of others, and how an individual thinks about their success, failures, skills, and strengths (Bong and Skaalvik, 2003). Research shows that having a positive self-concept is linked to self-esteem, wellbeing, and resilience in the face of negative stereotypes and racial discrimination (Bong and Skaalvik, 2003; Steele, 1997; Webber et al., 2013). Self-efficacy is a concept also important for mana motuhake. Self-efficacy is the degree to which an individual believes they have the skills and capabilities to achieve certain goals, which "influence[s] how people think, feel, motivate themselves and act" (Bandura, 1995, p. 2). Positive self-efficacy fosters motivation and achievement (Bong and Skaalvik, 2003). These concepts are important as academic self-concept and academic self-efficacy are derived from how an individual sees their academic selves generally (Diseth et al., 2014) and how they perceive their ability and capacity for growth in an academic context (Vestad et al., 2021).

The mana model posits that students' social identities, particularly ethnic and cultural identities, are central to developing mana motuhake. This is because self-concept and self-efficacy are bolstered by positive ethnic and cultural identity. As discussed previously in this chapter, individuals are aware of the societal view (including stereotypes) of their social categorizations (such as ethnic and cultural groups) and this can contribute positively or negatively to their self-concepts. Establishing strong and positive affiliations with one's social identity can reduce the negative impact of discrimination and racism and the subsequent impact on self-concept (Neblett et al., 2012; Sellers et al., 2006), and academic engagement and achievement (Webber, 2012). For instance, Macfarlane et al. (2014) found that successful Māori students had positive Māori identities and that families and community played a significant role in fostering this sense of identity. Whakapapa (knowledge and engagement in genealogy) and tribal knowledge were foundational to Māori identity and developed cultural efficacy for students (Webber and Macfarlane, 2020). Houkamau and Sibley (2011) suggest that cultural efficacy improves wellbeing because it indicates affinity with Māori others, resulting in social support and a sense of belonging. This aligns with international research that links positive ethnic identity with desirable psychological outcomes for Indigenous and minority groups (Dockery, 2010; Martinez and Dukes, 1997; Williams et al., 2018). Martinez and Dukes (1997) argue that education focused on strengthening student's ethnic identities and understanding race relations will benefit the wellbeing, self-esteem, self-confidence, and purpose in life for all students.

Connectedness, awareness of racism and embedded achievement are considered three vital components of a strong racial-ethnic identity which supports student success despite contextual circumstances (Oyserman et al., 1995; Altschul et al., 2006). Within this, it is important student know that they are capable of achieving *because* of their ethnic and cultural identity and knowledge. Embedded achievement is the belief that (ethnic) group membership is associated with valuing and succeeding in education (Oyserman and Lewis, 2017, p. 162). Having a sense of embedded achievement fosters resilience by pushing against the stigma that many Indigenous groups face. Thus, Indigenous perspectives posit that motivation and resilience at school is rooted in students' self-concept and self-efficacy, which crucially involves their ethnic and cultural identities (Webber and Macfarlane, 2020). As a result, strong ethnic and cultural role models are vital for inspiring embedded achievement and aspirational academic and personal goals for Māori students. It is important that education environments engage students by highlighting that "people like them" belong in certain domains (Highfield and Webber, 2021). The Mana Model is based on the assertion that all students are capable, and that academic, social, and cultural efficacy can provide them with the confidence and self-belief to thrive.

Mana tū—social psychological competence

Mana tū, highlights the social psychological competencies that students need in order to persevere through the challenges they may face. The Maori word *tū* refers to an individual's firm stance or ability to stand strong. From a Mana tū perspective, success involves social and mental wellbeing so that individuals can drive their own success. Mana tū describes the environmental and personal characteristics that strengthen students' capacity to work toward success. Holistic familial support is also an important environmental factor because family play a critical role in terms of modeling resilience strategies to students. Some students also utilized cultural supports (traditions, beliefs and family) to respond to challenges (Webber and Macfarlane, 2020).

Successful Māori students demonstrate personal characteristics such as resilience, academic persistence, grit, tenacity, and perseverance. These characteristics align with previous research that has shown that characteristics such as grit, perseverance, and consistency can aid academic achievement (Akos and Kretchmar, 2017; Bowman et al., 2015; Strayhorn, 2014; Credé et al., 2017; Duckworth et al., 2007; Wolters and Hussain, 2015) because they boost motivation, strategy use, and through avoiding

procrastination (Wolters and Hussain, 2015). In addition, resilience enables Māori students to overcome challenges and achieve positive outcomes (Masten, 2001, 2014). Resilience is beneficial for all students but particularly vital for Indigenous students who “are more likely to experience high levels of cumulative and co-occurring risks that lower their resilience, engagement, and participation in education” (McCalman and Bainbridge, 2021, p. 199). As Durie (2011) states,

Indigenous resilience is a reflection of an innate determination by Indigenous peoples to succeed. Resilience is the polar opposite of rigidity. It provides an alternate perspective to the more usual scenarios that emphasize Indigenous disadvantage, and allows the Indigenous challenge to be reconfigured as a search for success rather than an explanation of failure (p. 30).

Resilience offers a strengths-based approach to Indigenous education (McGuire-Kishebakabaykwe, 2010) and a positive lens for Indigenous students to see themselves.

Research shows that students benefit from being able to self-reflect on their thoughts feelings and behaviors in order to regulate and direct their own learning and learn from their past successes and failures (Grant et al., 2002; Voskamp et al., 2020; Colomer et al., 2021; Zimmerman, 2015). Self-reflection is also linked to insight (Hixon and Swann, 1993). When students have insight they understand themselves well and have clarity in who they are and what they need to do to succeed (Grant et al., 2002). Insight in particular is linked to positive wellbeing (Harrington and Loffredo, 2010; Lyke, 2008). This is mediated by the ability to maintain a positive outlook (Stein and Grant, 2014).

Mana tangatarua—diverse knowledge base and skillset

Indigenous perspectives of success recognize that many students traverse two or more worlds, each with differing sets of expectations, norms, and values. Mana tangatarua makes reference to the idea that many Indigenous students have the ability to maintain mana in two or more worlds. This concept is underpinned by the assertion that “academic success should never come at the expense of Māori identity” (Webber and Macfarlane, 2020, p. 41). This echoes the work of Durie (2011) who stated, “[i]t is no longer acceptable that education and training should lead to the abandonment of an Indigenous identity” (p. 33). Cultural identity and academic identity are both considered important facets of student’s identities, neither more important than the other. Schools tend to focus on individualized educative goals, which are important, albeit not the entirety of success from an Indigenous perspective.

Findings from the Ka Awatea study found that Māori students were grounded and led by their Māori identity (Macfarlane et al., 2014; Webber and Macfarlane, 2020), indicating that cultural/ethnic identity is central to mana tangatarua. Research in Aotearoa New Zealand and overseas has also shown that racial-ethnic identity is strengthened by cultural connectedness (Webber et al., 2013; Oyserman et al., 1995; Altschul et al., 2006) and that cultural connectedness positively impacts mental health outcomes for youth (Snowshoe et al., 2015; Fleming et al., 2020). Furthermore, cultural connectedness develops cultural efficacy (Houkamau and Sibley, 2011) which is “a person’s perception of his/her own capability to function effectively in situations characterized by cultural diversity” (Briones et al., 2009, p. 301). This capacity is rooted in knowledge of one’s own culture and history which enables students to appreciate and learn from the cultures of others. Since wider society and education typically reflects the dominant culture, many Indigenous students do not have their cultural identities developed at school (Milne, 2009; Zdrenka et al., 2015). Student’s families and communities are therefore vital and rich cultural resources for students to develop cultural connectedness, knowledge, and efficacy and for schools to support this (Webber et al., 2013; Webber and Macfarlane, 2020).

To walk in two (or more worlds), students need to be able to navigate the educational expectations and school culture while maintaining a sense of belonging and pride to their respective cultural groups. Importantly, a strong racial-ethnic identity is aided by an awareness of racism (Oyserman et al., 1995; Altschul et al., 2006). A large body of research exists pertaining to the obstacles Indigenous and other minority students face such as systemic and interpersonal racism, discrimination, and stereotypes (Benner et al., 2018; Cormack et al., 2018; Fisher et al., 2000; Turner et al., 2015). These factors create unique personal, social, economic, and educational barriers for Indigenous students. An awareness of how racism is a symptom of (colonial) history and wider societal issues can help to depersonalize negative racial experiences (Neblett et al., 2013). For Māori, an awareness of racism can help build resilience (Webber, 2015) and protect mental health (Houkamau and Sibley, 2011). Cultural connectedness coupled with an awareness of racism can improve student achievement (Altschul et al., 2006) and protect against the negative influence teacher discrimination can have on achievement (Thomas et al., 2009).

Conversely, dominant students can also benefit from understanding their own culture, particularly as many students do not see themselves as having a culture due to dominant culture being presented as the norm (Milne, 2009; Webber et al., 2013). Furthermore, through learning from the culture of others and about history and racism, dominant students, teachers, and wider community can gain perspective on the assumptions in education and beyond and the privileges that many benefit from as a result that (Small, 2019). Therefore, from an Indigenous perspective, it is important that student’s families, school environment, and local community provide support and learning opportunities with both cultural and educational foci (Webber and Macfarlane, 2020).

Conclusion

SIT suggests that Indigenous students' social identities are influential in how they see themselves and interact with others. Importantly, SIT posits that Indigenous students are motivated to achieve a positive sense of social identity which is largely established through comparison with other groups. Thus, while being a part of a socially valued or dominant group can bolster self-esteem, membership in a less socially valued or non-dominant group threatens self-esteem. This negatively impacts on Indigenous students' behavior and engagement at school. Similarly, stereotype threats are the persistent generalized, and often negative, assumptions and perceptions of one's social group that are an additional obstacle for Indigenous students. Stereotype threat impacts Indigenous student achievement and can be ruinous in terms of Indigenous students disengaging from school, or education as a whole, for fear of being confirming negative stereotypes.

This chapter has considered how Indigenous social-psychological theory, and research conducted in Aotearoa New Zealand with Māori students, might offer a useful perspective on identity formation and how schools and educators might best support students' social identities and develop student resilience against stereotype threat. The chapter presents the Mana Model, and a number of ways schools might better support the diverse social identities of Indigenous students and ensure that they do not need to choose between their cultural identity and their academic identity to achieve at school. When schools work to support students' social identities and foster their connection to their culture, community and peers, there is a positive impact on students individually as well as on their academic engagement and outcomes. Furthermore, when students develop mana in various facets of their lives as outlined by the mana model, resilience is fostered, and stereotype threat is mitigated.

There is growing consensus that the nature and quality of children's relationships with their teachers play a critical and central role in motivating and engaging students to learn and to behave in socially-acceptable ways (see [Wentzel, 2016](#)). Effective teachers are typically described as those who develop relationships with students that are emotionally close, safe, and trusting, that provide access to instrumental help, and that foster a more general ethos of community and caring in classrooms. In doing so, they support the development of students' emotional well-being and positive sense of self, motivational orientations for social and academic outcomes, and actual social and academic skills. They also provide a context for communicating positive and high expectations for performance and teaching students what they need to know to become knowledgeable and productive citizens. Likewise, children who enjoy positive relationships with their peers also tend to be engaged in, and even excel at, academic tasks and display positive forms of behavior more than those who have peer relationship problems (see [Wentzel and Muenks, 2016](#)). As with teachers, positive relationships with peers also appear to afford opportunities for developing levels of trust and safety, receiving help and information concerning what is expected of them academically and socially.

A focus on the social ecologies of schooling reflects the notion that the ability to be competent in any social setting, including classrooms and schools, is contingent on opportunities and affordances of the social environment. [Bronfenbrenner \(1989\)](#) argued that competence is achieved, in part, when contexts provide opportunities for the growth and development of personal skills and attributes as well as scaffolding for learning what is expected by the social group. Expanding on this notion of situated competence, [Ford \(1992\)](#) argued that several contextual supports can promote positive social engagement, including information concerning what is expected and valued, help and instruction that support attempts to achieve these valued outcomes, a safe, non-threatening environment; and emotional involvement such that individuals are made to feel like a valued member of the group.

Using this ecological approach as a guiding framework, I first review the literature on teacher–student and peer relationships as it pertains to children's school-related competencies: specifically, motivation to engage socially and academically, academic achievement, and social-behavioral outcomes. I then describe the benefits and affordances of these relationships in competence development, including communications of norms and expectations, instrumental aid, emotional support and safety, and rewards and reinforcements.

Interpersonal relationships with peers and teachers

Within school contexts, positive interpersonal relationships are valued outcomes in and of themselves; they also are necessary for successful group functioning and appear to be significant motivators of student outcomes. In the following sections, literature on teacher–student and peer relationships and their associations with student motivation, academic achievement, and social-behavioral outcomes is described.

Relationships with teachers

Evidence to support the importance of teacher–student relationships in students' lives has increased tremendously in the past ten years. Research has focused primarily on attachment-like qualities of dyadic teacher–student relationships, and students' perceptions of supports from teachers (see [Wentzel, 2016](#) for a review). In young children, this typically takes the form of attachments to teachers and relationship qualities reflective of warmth and emotional caring (e.g., [Pianta, 2006](#)). In older children, researchers tend to focus on students' subjective appraisals of their relationships with teachers (e.g., teacher emotional involvement) and teachers' emotional support (e.g., [Wentzel et al., 2016](#)). In contrast, not all teacher–student relationships are positive. They also can be marked by conflict, criticism, and distrust ([Brinkworth et al., 2018](#)), and characterized by ineffective teaching, lack of help, and inattention to students' needs for autonomy and relatedness ([Liu et al., 2018](#)).

The literature on teacher–student relationships and student outcomes is described next.

Teacher–student relationships and motivation

Teacher–student relationships marked by emotional closeness and emotional support has been related significantly to students' motivation throughout the school-aged years, including school liking, students' mastery and performance goal orientations, academic values, interest, engagement, and self-efficacy (see [Wentzel, 2016](#) for a review). In addition, when students perceive their relationships with teachers as caring and emotionally supportive, they are more likely to report satisfaction of needs for autonomy, relatedness, and competence (see, Self-Determination Theory, [Deci and Ryan, 2002](#); [Froiland et al., 2019](#)). Over the course of a school year, perceived emotional support from teachers has predicted a positive sense of autonomy, engagement and mastery motivation ([Dietrich et al., 2015](#); [Ruzek et al., 2016](#)), a sense of community and collective efficacy (a belief in the ability to achieve common goals; [Bandura, 1986](#)), and a sense of positive well-being ([Capone et al., 2018](#)).

Other researchers have documented a cumulative effect of teacher–student relationships such that the greater number of positive relationships students have with teachers, the more likely they are to participate in academics, enjoy their work, and aspire to higher levels of education ([Martin and Collie, 2019](#)), and less likely to experience emotional distress and anxiety at school ([Connor et al., 2014](#)). Finally, in a review of 46 studies of teacher–student relationships, [Quin \(2017\)](#) concluded that positive relationships with teachers were related to students' attendance, and grades, even when taking into account other personal, family school and teacher characteristics.

Teacher–student relationships and achievement

Meta-analyses have documented significant relations between positive teacher–student relationships and academic outcomes in young children (e.g., [Kincaid et al., 2020](#)). [Hamre and Pianta \(2001\)](#) found kindergartners' relationships with teachers marked by conflict and dependency predicted lower grades and standardized test scores over the course of eight years. Meta-analytic studies also have linked perceived emotional support and positive relationships with teachers consistently to academic achievement in older students ([Quin, 2017](#); [Roorda et al., 2011](#)).

Teacher–student relationships and social-behavioral outcomes

Positive teacher–student relationships also have been related to students' socially competent behavior, whereas relationships marked by conflict have been related positively to children's aggressive and socially incompetent behavior and peer rejection (e.g., [Ladd and Burgess, 2001](#)). [Hamre and Pianta \(2001\)](#) documented associations between teacher–student conflict in kindergarten and fewer positive work-habits and increased numbers of disciplinary infractions through eighth grade, especially for boys. Other longitudinal studies have documented that qualities of teacher–student relationships in Kindergarten predict social-emotional outcomes in first and second grade (e.g., [Peisner-Feinberg et al., 2001](#); [Pianta and Stuhlman, 2004](#)). In older samples, positive teacher–student relationships have been related to students' social-emotional functioning, including prosocial and responsible behavior ([Wentzel, 2013](#)). Students' appraisals of teacher emotional support also have been related to students' pursuit of goals to behave in prosocial and responsible ways (see [Wentzel, 2016](#) for a review of this research).

Relationships with peers

Positive relationships with peers also have been related consistently to a range of positive academically-related accomplishments ([Wentzel, 2017](#)). However, unlike teacher–student relationships, peer relationships have been studied in a variety of ways,

including dyadic friendships, the degree of peer acceptance by the larger peer group, and membership in specific peer groups (see, [Juvonen et al., 2012](#); [Wentzel, 2017](#)). Peer relationships also are examined within structured interactions related to instruction (e.g., cooperative and collaborative learning; see, [Wentzel et al., 2021](#); [Wentzel and Watkins, 2011](#)).

To assess dyadic friendships, researchers ask students to nominate their best friends at school; often, nominations are then matched to determine reciprocity, or best friendships. Peer acceptance and social (e.g., sociometric) status is typically determined by unilateral assessments of a child's relative standing or reputation within a larger group of peers, such as a group of classmates. Based on these assessments, students are assigned to a sociometric status group (i.e., popular, rejected, neglected, controversial, and average status; see [Asher and Dodge, 1986](#)), or described in terms of overall acceptance or rejection by peers. As such, peer acceptance or social status of a student is determined by a diverse set of peers who are not necessarily friends with the student and with whom interactions might be infrequent.

Membership in peer crowds and groups is typically determined by identifying clusters of students who are friends with each other using statistical procedures (e.g., [Kindermann and Gest, 2009](#)) or by asking students to identify groups characterized by activities (e.g., sports) or behavioral characteristics (e.g., substance use) or, more simply, those who spend time together (e.g., who hangs out with whom) ([Brown, 1989](#)). Students' membership in specific peer crowds and groups has been studied most frequently in adolescent samples (see [Brown, 1989](#); [Brown and Dietz, 2009](#)). Adolescent crowds often include "Populars" ("Popular" crowds are often described in negative terms such as being dominant and exclusionary ([Parkhurst and Hopmeyer, 1998](#)), or in terms of students who engage in positive forms of academic as well as social behavior), "Jocks" (characterized by athletic accomplishments), "Druggies" (engaged in delinquent and other illicit activities), and "Normals" (fairly average students). Research on peer crowds has been mostly descriptive, identifying the central norms and values that uniquely characterize each crowd. A related construct, peer networks, reflects groups of students formed on the basis of mutual friendships.

The central distinction between having friends and involvement with larger peer groups is that friendships reflect relatively private, egalitarian relationships often formed on the basis of idiosyncratic criteria. In contrast, peer groups are defined by publicly acknowledged and therefore easily identified and predictable characteristics that are valued by the group. In addition, whereas friendships are enduring aspects of children's peer relationships at all ages, peer groups and crowds emerge primarily during middle school, peak at the beginning of high school, and then diminish in prevalence as well as influence by the end of high school ([Brown, 1989](#)).

Each of these peer relationship "types" has been studied in association with students' school-based functioning, including students' motivation, achievement, and social-behavioral outcomes. This literature is described in the following sections.

Peer relationships and motivation

A broad range of motivation outcomes have been studied with reference to peers (see [Kindermann and Skinner, 2012](#); [Wentzel, 2017](#); [Wentzel and Muenks, 2016](#), for reviews). Sociometric status and peer acceptance have been related to pursuit of goals to learn, interest in school, and perceived academic competence across the school-age years. In kindergarten, children who are rejected by their peers tend to engage in class activities less often than those who enjoy high levels of peer acceptance, and they report strong desires to avoid school; having friends is associated with positive school affect and school liking. In older elementary school students, peer acceptance has been related positively to academic self-concept over time ([Flook et al., 2005](#)), while peer rejection has been linked negatively to children's self-concept and school engagement ([Buhs, 2005](#)).

During middle school, having friends has been related to positive aspects of academic and social motivation and engagement in school-related activities. Peer group membership has been associated with liking and enjoyment of school, and pursuit of learning-related goals over time. During high school, peer acceptance and group membership also have been related to a range of motivation outcomes (e.g., goals, efficacy, interest, effort). In addition, elementary-age students tend to self-select into groups of peers that have motivational orientations to school similar to their own and these orientations often become stronger and more similar within groups over the course of the school year (e.g., [Kindermann, 1993](#)). Similar findings have been reported in middle school samples (e.g., [Wentzel and Caldwell, 1997](#)).

Peer relationships and academic achievement

Peer relationships also have been related to academic achievement. Classroom grades and IQ have been related consistently to peer status and acceptance for elementary-aged children as well as adolescents (see [Cillessen and van den Berg, 2012](#); [Wentzel, 2017](#) for reviews). In kindergarten and elementary school, children who are rejected by their peers tend to perform less well on tests of achievement in comparison to those with positive peer relationships. Longitudinal studies have documented the stability of relations between peer acceptance and academic accomplishments over time.

Friendship also has been associated with academically-related outcomes (e.g., [Wentzel et al., 2021](#)). Simply having friends has been related positively to grades and test scores at all ages, whereas students without a reciprocated friend tend to adjust less well to academic demands. The power of peer groups and crowds to influence academic achievement is supported by findings that adolescent peer groups differ in the degree to which they pressure members to become involved in academic activities ([Brown and Dietz, 2009](#)).

Peer relationships and social-behavioral outcomes

An extensive body of work has documented associations between peer acceptance and social behavioral outcomes (see [Wentzel, 2013](#); [Wentzel and Muenks, 2016](#) for reviews). In general, socially accepted and popular students at all ages tend to be more pro-social and sociable and less aggressive, and rejected students less compliant, less self-assured, less sociable and more aggressive and withdrawn. Students' friendships and peer groups also have been associated with social-behavioral outcomes. Children with friends tend to be more sociable, cooperative, and self-confident when compared to their peers without friends; children with reciprocated friendships also tend to be more independent, emotionally supportive, altruistic and prosocial, and less aggressive than those who do not have such friendships ([Newcomb and Bagwell, 1995](#)). As with peer acceptance, these findings appear to be robust for students of all ages.

Relationship provisions and affordances

As summarized above, aspects of students' relationships with teachers and peers are related to motivation, achievement, and social-behavioral outcomes, and these findings appear to be robust for school-aged children from Kindergarten through high school. Of additional interest in the field is why these relationships and interactions predict positive outcomes at school. One approach to this issue has been to the benefits of and the social supports afforded by interactions and ongoing relationships with teachers and peers.

Relationship provisions or supports that are most likely to occur at school are: communications concerning norms and expectations, instrumental help, emotional support and safety, and rewards and reinforcements. Specifically, students will come to value and subsequently pursue academic and social goals valued by teachers and peers when they perceive their interactions and relationships with them as providing clear direction concerning goals that should be achieved; as facilitating the achievement of their goals by providing help, advice, and instruction; as being safe and responsive to their goal strivings; and as being emotionally supportive and nurturing (see, [Ford, 1992](#); [Wentzel, 2018](#)). In this manner, students' school-based competencies are a product of social reciprocity between a student and her teachers and classmates. Just as students must behave in ways that meet the expectations of others, so must teachers and peers provide support for the positive cognitive and social-emotional functioning of students. These supports are described in the following sections.

Communicating norms and expectations

Norms and expectations are communicated primarily by way of input from teachers and peers. In general, they concern socially-valued goals and expectations for academic performance and social behavior, and standards against which judgments of personal efficacy can be made. In other words, they define, clarify, maintain, and enforce academic and social norms.

Teachers

Teachers who create a dependable classroom structure provide students with the information and assistance they need to learn successfully. Structure is created by communicating expectations clearly; by responding consistently, predictably, and contingently to students' behavior; by offering help and support to those who are struggling; and by adjusting teaching strategies to individual differences. These practices promote a climate of interpersonal trust and fairness that promotes students' willingness to listen to teacher communications and adopt desired behavioral and learning goals and values. Students who experience optimal levels of this kind of structure are likely to be the most effortful, persistent, and highly engaged in classroom activities ([Skinner and Belmont, 1993](#)).

Teachers also convey expectations about ability and performance to individual students. As part of ongoing interpersonal interactions, these communications have the potential to influence a student's beliefs about her own ability and goals to achieve academically, especially when teachers' expectations result in their differential treatment of students ([Weinstein, 2002](#)). These expectations can reflect beliefs that students are able to achieve more than previously demonstrated, or reflect underestimations of student ability. The effects of these latter negative expectations appear to be fairly weak and short-lived, although they can serve as powerful self-fulfilling prophecies that can have stronger effects on students who are African-American, from low socio-economic backgrounds, and low achievers (see [Jussim et al., 2009](#)). In contrast, teachers' overestimations of ability seem to have a somewhat stronger effect in raising levels of achievement, especially for low performing students ([Madon et al., 1997](#)). Therefore, teachers who communicate high expectations for individual students can bring about positive changes in academic accomplishments.

Peers

Peers can be especially influential in communicating norms and expectations. Peers who convey expectations that academic engagement and positive social interactions are important and enjoyable are likely to lead others to form similar values and goals ([Bandura, 1986](#)). Empirical evidence that peers communicate expectations and opinions is suggested in findings of associations between

peer group membership and student outcomes (e.g., Kindermann, 1993; Kiuru et al., 2007). To illustrate, Hamm et al. (2013) found that middle school students who had sustained membership in a social network with norms supportive of effort and achievement were more likely to value school. With respect to behavioral outcomes, perceived expectations from peers for behaving prosocially are significant predictors of internalized values for and displays of prosocial behavior (Wentzel et al., 2007); peer communications concerning antisocial behavior appear to increase levels of aggression and misconduct at school (Ehrenreich et al., 2014).

Modeling is also a powerful process by which information is communicated. For example, students might develop specific behavioral styles or interests because they are desirable characteristics modeled by their peers (e.g., Barry and Wentzel, 2006). Children utilize their peers for comparative purposes as early as four years of age (Butler, 2005). Elementary school students have been found to choose difficult academic goals for themselves only when they observe a peer who prefers difficult academic goals (Sagot-sky and Lepper, 1982). Peer modeling is also particularly effective for supporting positive academic self-efficacy. As children work on academic tasks that require fairly specific skills and are evaluated with respect to clearly defined standards, they use each other to monitor and evaluate their own abilities (Schunk and Pajares, 2009).

Modeling effects seem to be especially likely to occur when students are friends (e.g., Ricciardelli and Mellor, 2012). Although evidence is indirect, changes in young children's competence perceptions from fall to spring have been associated with the competence perceptions of their very best friends. Adolescents' perceptions of their friends' achievement-related behavior, engagement, and academic performance have predicted their own self-concept, achievement-related choices, goal pursuit, engagement, and academic performance (see, Wentzel, 2018).

Finally, the influence of peer crowds on adolescent functioning is illuminated in ethnographic studies that describe how peer crowds facilitate the formation of students' identity and self-concept and structure their ongoing social interactions (Brown, 1989). With respect to identity formation, crowds are believed to provide adolescents with values, norms, and interaction styles that are sanctioned and commonly displayed. Behaviors that are characteristic of a crowd are modeled frequently so that they can be learned easily and adopted by individuals. In this manner, crowds provide prototypical examples of various identities (including that of being a good student) for those who wish to "try out" different lifestyles and, in doing so, can affirm an adolescent's sense of self.

It should be noted that peer expectations concerning appropriate behavior will contribute to the development of competencies valued by teachers and other adults only insofar as the peer group believes that adult standards for achievement and norms for conduct are important and legitimate. As children enter adolescence, however, they are less likely to acknowledge the legitimacy of adult-imposed norms (Smetana and Bitz, 1996) or automatically enforce classroom rules (Eccles and Midgley, 1989). Therefore, dependence on peers to communicate and enforce adult-generated rules might not be appropriate for many older students.

Instrumental aid: provisions of help, advice, and instruction

Instrumental aid in the form of help-giving, advice and direct instruction is a powerful support that facilitates students' academic and social adjustment to school. Social cognitive theory (Bandura, 1986) suggests that direct instruction and modeling of skills are especially powerful mechanisms whereby students learn the skills that enable them to go about meeting teacher and peer expectations.

Teachers

Teachers play the central role of transmitting knowledge and training students in academic subject areas by providing information and advice, modeled behavior, or specific experiences that facilitate learning as well as interpersonal competence. Brophy and Good (1974) documented the relevance of teachers' relationships with elementary-aged students for gaining access to academic resources. Teachers in their study reported that they were more appreciative and positive toward students who were cooperative and persistent than toward students who were less cooperative but displayed high levels of creativity and achievement. Teachers also responded with help and encouragement to students about whom they were concerned when these students sought them out for help. In contrast, students toward whom they felt rejection were treated most often with criticism and typically were refused help.

Peers

Students also communicate important information, teach valuable skills, and provide instrumental help to each other. Help giving is perhaps the most explicit and obvious way in which peers can have a direct influence on students' academic and social competence. During adolescence, students report that their peers are as or more important sources of instrumental aid than their teachers (Lempers and Clark-Lempers, 1992). Peers also provide input concerning reasons for engaging in academic tasks (e.g., because it is important or fun; Wentzel, 2004). Finally, advice and feedback from peers following success or failure can lead to adjustments in perceived competence and expectations for future success (e.g., Altermatt et al., 2002).

Social and emotional support and safety

A number of theoretical perspectives, including attachment theory (e.g., Bretherton, 1987), social support perspectives (Sarason et al., 1990) and self-determination theory (Ryan and Deci, 2000) propose that receiving emotional support conveys a message that one is a valued and integral member of a relationship or of a larger social group (Connell and Wellborn, 1991). In turn, feelings of emotional security and being socially connected are believed to facilitate the adoption of goals and interests valued by others, including goals to contribute in positive ways to the overall functioning of the social group (e.g., Deci and Ryan, 2002). This appears to be the case both for teachers and peers.

Teachers

In conjunction with communicating clear expectations and providing instrumental help, teachers also create contexts characterized by levels of emotional support and personal safety (Connell and Wellborn, 1991). As noted earlier, emotionally supportive relationships have the potential to influence student motivation, achievement and social-behavioral outcomes. An additional aspect of teachers' emotional support is reflected in their efforts to protect students' physical well-being. Most frequently, issues of student safety are discussed, with regard to peer interactions, in the form of aggression and bullying. However, teachers can play a central role in creating classrooms that are free of peer harassment and in alleviating its negative effects once it has occurred (Olweus and Limber, 2009). Of special interest are findings that students are more likely to enjoy affectively positive relationships with teachers when they feel safe at school (e.g., Crosnoe et al., 2004).

Teachers also can promote positive classroom climates by providing students with help in forming positive relationships with each other. Although not much research has been done in this area, several conclusions can be drawn. First, teacher communications and instructional practices can influence peer relationships. For example, young students appear to be aware of the ability and behavioral expectations their teachers hold for their fellow classmates and tend to reject or accept their peers based on these perceived expectations (e.g., Donohue et al., 2003). In addition, students tend to have more close friends and a greater number of friends, and are less likely to experience peer rejection when teachers use learner-centered practices (e.g., involving students in decision making) as opposed to teacher-centered practices (e.g., focusing on rote learning, norm-referenced evaluation; Donohue et al., 2003).

Evidence also suggests that teachers who are more attuned to the peer dynamics of their classrooms tend to have greater influence over the social cultures of their classrooms than those who are not attuned. Teacher attunement to peer groups has been related to students' sense of school belonging, levels of peer acceptance, and with greater intolerance and disapproval of bullying and aggression among students (Hamm et al., 2011). Finally, perhaps the most straightforward method of promoting positive relationships among students is to employ cooperative learning activities as part of instruction. Cooperative learning activities offer motivational benefits because they respond to students' relatedness needs, as well as potential learning benefits because they engage students in the social construction of knowledge (see, Slavin et al., 2003).

Peers

Also noted earlier, students who perceive that their peers care about them tend to be interested and engaged in academic pursuits and positive forms of behavior, whereas students who do not perceive their relationships with peers as positive and caring tend to be at risk for motivational and academic problems and displaying antisocial behavior. The impact on school-related functioning likely comes from the positive opportunities and supports afforded to children with accepted peers, such as effective role models, direct instruction concerning normative behavior and skill development, and sources of positive reinforcements for social and academic behavior. The importance of social acceptance and rejection for understanding student motivation is underscored by findings that strong affective bonds and perceived support from others can serve as buffers from stress and anxiety and contribute to a positive sense of emotional well-being (Sarason et al., 1990). In turn, these positive feelings are believed to facilitate the adoption of goals and interests valued by others (e.g., Deci and Ryan, 2002).

In addition, students who are accepted by their peers and who have established friendships with classmates also are more likely to enjoy a relatively safe school environment and less likely to be the targets of peer-directed violence and harassment than their peers who do not have friends (e.g., Schwartz et al., 2000). Theorists also have argued that goals to sustain positive group identity and cohesion can result in exclusionary practices within and between groups (e.g., Bennett, 2014), including the formation of stereotypes and discriminatory practices (e.g., Dovidio et al., 2005). These group-level processes can have a profound effect on students' emotional well-being (Brown et al., 2008), their access to opportunities and supports (Haslam et al., 2012), and motivational beliefs, including a sense of group efficacy (Bandura, 1986).

The general effects of peer harassment on student motivation and academic competence have not been studied frequently. However, students who are frequently victimized also tend to report higher levels of distress and depression than those who are not (e.g., Kochenderfer-Ladd and Wardrop, 2001). Few studies have identified pathways whereby peer victimization affect academic outcomes. However, as with perceived support, peer abuse and exclusion is likely to be associated with academic achievement by way of emotional distress (Buhs, 2005; Flook et al., 2005). Therefore, although indirect, having supportive peers in these negatively charged situations can have positive effects on a wide range of social, motivational, and academic outcomes.

Rewards and reinforcements

Teachers and peers can also exert influence by way of reinforcements and rewards. These reinforcements can be extrinsic, conveyed through tangible benefits (e.g., help, social inclusion, or exclusion), feedback and instruction (e.g., praise or criticism), and coercive strategies (e.g., bullying, persuasion). They also can be intrinsic in that students might engage in behavior valued by teachers and peers because they experience it as enjoyable and of personal value.

Teachers

An extensive literature has documented ways in which teachers administer rewards to students through instruction, feedback, and behavioral management strategies (see [Wentzel, 2020](#), for a review). For example, instructional strategies that involve competition, salient rewards (e.g., food, stickers, free time), or public feedback reflect extrinsically-motivating strategies that can lead to perceptions by students that engaging in the activity is controlling and a threat to autonomy and choice. These effects are especially powerful when students perceive themselves to be engaged in academic tasks in order to please an authority figure, obtain a reward, or escape punishment. However, extrinsic rewards can also be valuable because they send a message concerning what students are supposed to do to achieve success in school, whether or not they find activities interesting or enjoyable.

Peers

Peers have been studied most often with respect to negative reinforcements and reward systems. In this literature, peers' use of intimidation, power assertion, and negative reinforcement has been the focus of discussions concerning peer pressure and how peer groups function to establish normative standards and power hierarchies (e.g., [Cairns et al., 1989](#)). To illustrate, popular children often exert power over others by using social acceptance and status as a reward for compliance and conformity (e.g., [Sandstrom, 2011](#)). Simultaneous use of prosocial (positive rewards) as well as coercive and aggressive (negative reinforcement) tactics appears to be a particularly effective strategy to gain social control and power among peers (e.g., [Hawley et al., 2002](#)), and to solidify and maintain group norms and practices ([Cairns et al., 1989](#)). An extensive literature has also demonstrated how negative reinforcement in the form of physical and relational aggression results in a broad range of outcomes related to motivation, emotional functioning, and social behavior, for perpetrators as well as victims (e.g., [Crick et al., 2009](#)). With respect to academics, evidence suggests that students can experience negative reinforcement for doing well academically through labeling and stigmatization ([Boehnke, 2008](#)).

Summary

Support for a focus on relationship provisions at school is reflected in findings that expectations for academic performance, help, emotional support and safety, and rewards and reinforcements from teachers and peers have the potential to contribute to a broad range of motivational, achievement and social behavioral outcomes at all ages (see [Wentzel, 2013](#)). Clear communication and instrumental help in the form of direct instruction and modeling are powerful mechanisms whereby students learn what is expected of them and how to go about meeting those expectations. These mechanisms also can result in the development of skills and abilities that bolster one's sense of efficacy and positive beliefs about control over the learning process. Reinforcements and rewards from teachers and peers are additional and important sources of information concerning socially-valued goals, values, and perceptions of ability and control. These social cues convey to students the potential affective and interpersonal consequences if they do not behave or perform as expected. Finally, levels of emotional closeness, security and safety associated with teacher-student relationships can play a causal role in the development of a range of positive motivational outcomes in children.

Conclusions

There is no doubt that teachers and peers can have a powerful impact on a student's day-to-day life at school. Relationships and interactions that demonstrate essential supports and caring are important facilitators of student motivation, achievement, and a range of social competencies. It is troubling, therefore, that some researchers have reported that up to 25% of elementary-age students believe that school is an uncaring place ([Watson et al., 1989](#)). In middle school, these percentages can be even greater (e.g., [Wentzel, 1997](#)). In these cases, students feel alienated from the life of the classroom and become disengaged and unmotivated ([Legault et al., 2006](#)). In addition, research suggests that supportive relationships might be more important for some students than for others. For example, the literature on teacher-student relationships suggests that students from lower SES backgrounds and members of minority groups tend to benefit more from close relationships than do other students; school-level factors such as safety, racial homogeneity, SES of the student body, and composition of instructional teams also appear to impact the degree to which perceived support is related to student outcomes (see [Wentzel, 2016](#)).

These findings suggest that implementing programs to improve teacher–student and peer relationships should be a central component of school policy. Although intervention efforts have been infrequent, several programs appear to be promising and noteworthy. For example, the Responsive Classroom (RC) approach has been associated with improved teacher–student relationships and classroom behavior in addition to academic gains (Rimm-Kaufman and Chiu, 2007; Rimm-Kaufman et al., 2007). Designed to increase teachers' positive interactions with students and promote sensitive instructional practices, RC also has demonstrated improvement in positive peer interactions of students high in disruptive behavior (Mikami et al., 2012). The REAL program, which includes a focus on teachers' understanding of classroom social dynamics, also has demonstrated positive gains in students' motivation and academic outcomes, along with changes in peer norms for academic effort and achievement (Hamm et al., 2011). The Child Development Project (CDP; Developmental Studies Center) has been successful at improving classroom management practices and interpersonal relationships.

In addition, teachers and school administrators can play a central role in creating schools that are free of peer harassment and in alleviating the negative effects of harassment once it has occurred (e.g., Olweus and Limber, 2009). Interventions designed to offset the often negative influence of peer groups and gangs on behavior and school attendance are especially successful if students have access to adults who provide them with warmth and strong guidance (e.g., Chaskin, 2010). Schools that stress intergenerational bonding also support the development of positive teacher–student relationships that can act as buffers against the potentially negative effects of aggressive peers on behavior (Crosnoe and Needham, 2004). Utilizing these tools to improve teacher–student and peer relationships at school has the potential to support the development of school-based competencies for all children.

Formal education is highly valued commodity in nearly all cultures and societies. In western, capitalist counties in particular, school success has been linked to a variety of positive outcomes including higher incomes, enhanced social standing, higher self-esteem and even healthier and longer lives (Chowdhury, 2018; OECD, 2013). Conversely, school failure has been associated with poor health, low self-esteem and higher levels of unemployment and incarceration (OECD, 2013; Harlow, 2003; Marks, 2006). Given the stakes, it is no wonder that public education is the subject of fierce debates in the popular press, academic journals and the halls of government.

Despite the desire to leave “no child behind” (No Child Left Behind [NCLB], 2002), failure may be a built-in feature of modern schooling. Two taken-for-granted assumptions underlying schooling, for example, are that educational achievement distributes more or less “normally,” along the lines of a bell curve—meaning that fully half of students will achieve that status of “below average” (Dudley-Marling and Gurn, 2010; Annamma et al., 2013)—and that every student is expected to do better than everyone else (McDermott et al., 2006). Failure is a given in this situation.

Other analyses also implicate the institution of schooling and its employees for widespread school failure. Some economists, for example, have argued that the failures of public schooling can be traced to the lack of economic competition among schools (Friedman, 1955; Chubb and Moe, 1990). Public schooling is a monopoly and, therefore, indifferent to reform. From this perspective, school choice, in the form of vouchers and charter schools, is the remedy for failing schools (see Hursh, 2007 for a review of free market proposals for reforming public schooling). Other critics of public education have focused on the quality of teachers and teacher education. The influential National Council on Teacher Quality (NCTQ), for example, has repeatedly questioned teachers’ preparation for teaching reading, mathematics and content area subjects (NCTQ, 2021).

Whatever the inadequacies of modern public schooling, when individual children struggle to achieve at acceptable levels the tendency is to situate the *problem* in the minds and bodies of children who are presumed to be deficient in motivation, effort or abilities required for academic success. Children who struggle in school are assigned a variety of formal and informal labels by school officials ranging from learning disabled or intellectually impaired to at-risk, slow or struggling learners or simply “lazy.” Whatever the label, the presumption is that the *problem* is intrinsic to the child who must be remediated or “fixed.” An alternative, social constructivist narrative situates school failure outside minds and bodies of students in the complex web of human relations (Gergen, 1990). From this point of view, no one can fail (or succeed) in school on their own. As Collins and Ferri (2016) put it, learning difficulties are “not seen as a problem located in particular bodies or brains ... but rather as a social artifact created and maintained by a lack of fit between a particular learner and his or her context” (p. 8).

This paper begins with an overview of a social constructivist view of learning before turning to a social constructivist perspective on school failure. The final section considers the implications of a shift from an individualistic, deficit-oriented take on learning failure in schools to a socio-cultural perspective.

Social construction of learning

Conventionally, learning is understood to be an individual accomplishment mediated by parents, teachers and other more skilled persons. From this perspective, children learn to talk, read, and write, for example, by acquiring specific sets of skills associated with effective reading, writing, speaking and so on with the help of parents, teachers, siblings and other members of the community. Indeed, learning to speak or read, do math or just find your way to the store, is understood as the mastery of a set of specific skills. And, again, while no one learns completely on their own, learning is generally assumed to be largely the responsibility of the individual.

A social construction of learning offers a radically different perspective both on what is learned and how it is learned. To begin with, a social constructivist perspective holds that people do not learn to read, write, or speak “once and for all.” Instead, they learn to read, write, and speak in particular ways, for particular purposes and audiences, in particular social settings. (Gee, 2012). Specifically, reading, writing, and speaking (and other learning) are sets of social practices that enable participation in particular cultural activities in various cultural communities. Learning language, for instance, involves more than mastering a set of linguistic skills (vocabulary, syntax, etc.). Language practices always involve ways of behaving, thinking, interacting, valuing, believing, and

speaking, in short, becoming particular kinds of people (Gee, 2012). The use of language as part of a religious ritual, for instance, includes saying and doing just the right things in just the right way and the right time in the appropriate setting. Moreover, the right sort of clothing, demeanor, and attitude and beliefs will also be necessary for this social practice to “count” as a religious expression. In other words, participating in this social practice involves being a particular kind of (religious) person. Other social practices, entailing different purposes, settings, participants and so on, involve learning to become different sorts of people. In this sense, learning implies becoming a certain kind of person, indeed, becoming different sorts of people (i.e., different identities) in various social and cultural settings. In other words, what is learned are different relationships among and between people in various contexts; therefore, learning always involves the construction of identities (Lave and Wenger, 1991). Ultimately, the community will adjudicate learning, that is, whether people demonstrate they have learned by showing that they have learned to be the “right sort of person” in particular social/cultural settings.

A social construction of learning indicates that what people learn is largely about participating in various communities—including school. This is also where meaning resides since people always make sense from a particular (cultural) perspective. But this is not just about learning in (a social) context. The sociocultural context is not just where learning takes place or where knowledge is constructed; it is part of what is learned (Cole, 1996). What is learned is always social and, therefore, all knowledge carries social and cultural meanings. Even what appears to be solitary learning has social character since people learn as members of social and cultural groups and what they learn is related to social practices that are enacted in communities. Bakhtin famously argued that language—perhaps the most powerful of cultural tools—is far from a neutral medium since it is “overpopulated with the intentions of others” (Bakhtin, 1981, p. 294). Language, the learning tool extraordinaire, is saturated with social, cultural and historical meanings; therefore, learning mediated by language—as is usually the case for higher order learning—will always have a social character. Given that the primary tool for learning, language, is imbued with a social and cultural quality even what appears to be solitary learning has a social character.

From a social constructivist point of view, learning does not manifest (merely) in the minds and bodies of autonomous individuals. A social construction of learning emphasizes the profoundly social/cultural character of learning. Learning is a process that takes place in participation frameworks and it is in the context of engaging with these frameworks that people learn cultural activities (social practices) that make them into particular kinds of people (Lave and Wenger, 1991). However, people cannot participate or learn to participate in cultural activities or practices on their own. Effective participation in cultural practices always requires coordinated activity among members of the cultural community and, indeed, it is this coordinated activity that is learned. Moreover, coordinated action is *how* learning occurs and *where* it occurs.

The metaphor of a dance is a useful, if somewhat oversimplified, way to explicate this coordinated action in which various members of the community work (dance) together to perform social practices that enact particular (learning) identities—ways of being in the world—for each of the participants (dancers). Consider the context of formal school learning. The teaching-learning interaction can be likened to an intricate dance to which both students and teachers contribute. This dance is mediated by the curriculum, school policies, the culture of the school and classroom (and schooling more generally), the language of students and teachers, and so on. Take, for example, the classic *initiation* (teacher asks a question)—*response* (student answers the question)—*evaluation* (teacher evaluates the correctness of the student’s response) (IRE) paradigm. In the context of the IRE paradigm learning has a very particular meaning but for students to succeed—or fail—requires the coordination of a particular set of moves by the teacher and students. It also takes someone with the authority to adjudicate the student’s response, in this case the teacher. Importantly, different moves by the teacher (or the student) will alter the shape of the dance, potentially transforming students’ and teachers’ identities. If, instead of responding to an unexpected response by a student with an evaluation (the “E” in I-R-E), the teacher asks, “what do you mean?” she (potentially) transforms her relationship with her student and, ultimately, the meaning of learning. In either case, what students and teachers learn is a socializing routine, a particular set of moves or practices that “count” as learning in the classroom. They also learn an identity. In the case of I-R-E, students are positioned as “getters of the answer the teacher has in mind.” In the alternative example where the teacher responds to a “wrong” answer with “what do you mean?”, students are re-positioned as thinkers or explainers.

The meaning of coordinated actions—in this case school learning—also relies on just the right people doing just the right moves in a particular time and place. The I-R-E paradigm, for example, would signal a very different meaning performed outside the context of a classroom (in say, a bar) or if the evaluative move was performed by someone who had not been granted to the authority to adjudicate the performance of the other party.

The teaching-learning “dance” in a classroom has a particular character that sets it apart from other kinds of learning. But the concept of learning as coordinated action among particular people performing just the right action at the right time and place applies to all forms of learning, from learning to drive a car, learning to cook, learning to read, write, or speak, or learning to make love, to learning to solve a math problem. These are all social/cultural practices that are learned through the process of coordinated actions in contexts where these practices are being performed. From the perspective of a social construction of learning, learning is very much context specific, guided by others, and mediated by particular cultural tools and artifacts. Returning to the dance metaphor, learning the dance depends on people working together to accomplish a particular set of moves that will be recognized as dancing. These moves cannot be accomplished by a person acting on their own or without the aid of music and, perhaps, props (certain dances require specific clothing, spaces, types of music, etc.). Again, learning is never a solitary activity accomplished by autonomous individuals, nor is learning “failure” a solo accomplishment. Things (i.e., neurological activity) do go on in peoples’ heads, but those processes are inextricably linked to social, cultural, and historical factors. Learning is situated in relations among

people in coordinated activity in, with, and emerging from the socially and culturally constructed world (Lave and Wenger, 1991). This is what is learned, how it is learned, and where learning occurs.

If social/cultural practices are what, how and where people learn, it follows that learning resides in the practice and not just in people’s head; it is distributed across cultural practices in the actions of people as they participate in (cultural) activities, in the cultural tools (like language) that have been created as part of the practices, the social setting, and so on. Returning again to the dance metaphor, the “memory” of the dance simultaneously inhabits the dancers, the music, the venue created for the performance of the dance, even the dancers’ shoes and clothing. In other words, the memory of the dance is *in* the dance. Learning to participate in the school practice known as Initiation-Response-Evaluation—and any other school practice—resides in teachers, students, curriculum and testing materials, the physical organization of the classroom (teacher standing in front of students seated in rows) and, most of all, in the language teachers and students draw on to enact this practice. Ultimately, learning does not belong to individual persons, but to the various cultural activities or practices of which they are a part (McDermott, 1993). In this way, learning is distributed across people as they participate in culturally relevant activities (Robbins, 2005).

A social/cultural constructivist perspective on learning “problems”

Considerable attention has been given to the seemingly high proportion of school children who fail to achieve at acceptable levels (i.e., above average). These students are referred to by a range of formal and informal designations such as at-risk, struggling learners, learning disabled, intellectually challenged or just “below average.” Whatever the label, the popular assumption is that academic failure resides in the minds of individual students and, therefore, remediation focuses on “fixing” students’ deficiencies. An alternative discourse focuses on the role that the structures of modern schooling play in producing high levels of school failure. James Gee (2004), for instance, asks: what is there about schooling that transforms so many children who have repeatedly demonstrated that they are good at learning outside school into children who are not good at learning within the walls of schools? Cambourne (1995) puts it this way: “how could a brain which could master such complex learning in the world outside school be considered deficient with respect to the kinds of learning that were supposed to occur inside school?” (p. 183). McDermott et al. (2006) offer the following as an answer. “The American classroom is well organized for the production and display of failure, one child at a time, if possible, but group by group if necessary” (p. 13). Varenne and McDermott (1999) discuss how this process works:

A half-century of ethnographic studies has shown that American education is compulsively competitive. In American classrooms, every child not only has to learn, but to learn better or faster than his or her neighbors. As such, American education is well organized to make hierarchy out of any differences that can be claimed, however falsely, as natural, inherent, and potentially consequential in school. (p. 4)

The proof that some students have learned “better and faster” is the presence of students who fail. In other words, the success of some is determined in relation to the failure of others. Indeed, there is a sense in which school failure is inevitable, a *natural* outcome of the *normal* distribution of human behavior including academic achievement. Indeed, the elimination of school failure may be unacceptable to those who rely on the failure (of some) to affirm their own successes.

A social constructivist perspective challenges the school-failure-as-deficiency position by asserting that the performance of school failure requires the coordination of just the right people doing just the right things in just the right time and place. In the rest of this section, I offer a more detailed discussion of a social constructivist theory of school failure before considering what comes from that perspective.

Traditional psychology defines identity in terms of essential, often immutable traits that are presumed to be the possession of autonomous individuals (Shweder, 1990). It is generally assumed, for example, that people are happy or sad, outgoing or shy, smart or dull, engaged or distractible, calm or excitable and so on. It is never quite so simple as this, however. The happiest person is sometimes sad and even the dullest person can, occasionally, have brilliant insights. And, of course, a student labeled with a reading problem, for example, may have extraordinary mathematical abilities. Still, the popular assumption remains that, over time, there are more or less immutable, essential qualities that define who we are.

An alternative perspective rejects essentialist, in-the-head notions of identity in favor of the idea that identities, including learning identities, are always constructed in relation to other people engaged in coordinated activity in particular social and cultural settings. At the most basic level, “identity emerges in discourse through the temporary roles and orientations assumed by participants, such as evaluator, joke teller, or engaged listener” (Bucholtz and Hall, 2005, p. 591). Consider, for example, the quality of “smart,” which is generally considered to be an essential identity trait in Western cultures. The performance of *smartness* requires the production of certain behaviors valued by the culture (e.g., high academic achievement), performed at the right time and place (e.g., schools, certain workplaces), the presence of others authorized to adjudicate *smartness* (e.g., teachers, psychologists, supervisors) and, crucially, the presence of others deemed not to be smart. Ultimately, no one can perform the identities of smart, slow, at-risk or struggling learner on their own. People do bring various traits to the different contexts in which they live but it is the sociocultural context—full of actors, actions, institutional norms and so on—that gives meaning to these traits (Gee, 2000).

Consider the following example, which illustrates how the identity struggling learner emerged in an instructional interaction between a special education teacher, Mrs. Stroh, and Regis, a student for whom school was a struggle. In this excerpt Mrs. Stroh and Regis were discussing a picture he brought to school.

S: What are you doing in the picture?

R: Skating.

S: Will you tell me a sentence about it?

R: I go skating.

S: Where?

R: In the Mill Pond.

S: In the Mill Pond? Are you right in the pond?

R: Yeah. No.

S: No [laughs]. Where are you?

R: Skating.

S: Yes, but you're not in the Mill Pond. You'd be all wet if you were in it. Where are you?

R: Skating, I think. I don't know. Icing, I think.

S: Sometimes we say, “Skating at the Mill Pond.”

R: Yeah.

Through the lens of deficiency, this confused and confusing interaction lends credence to the school's assessment that there is something wrong with Regis, that he has a learning problem. Certainly, that's how Mrs. Stroh saw it. In a separate interview she indicated that this lesson demonstrated Regis's difficulties “expressing ideas.” Regis did seem to be having trouble expressing himself in relation to Mrs. Stroh's prompts, and even made up a word (“icing”) to describe where he was and what he was doing in the picture. However, from Regis's point of view, this miscommunication may have occurred because one conversational partner (the teacher) treated Regis's utterances as nonsense (Gergen, 1990) and Regis seemed more than a little mystified by Mrs. Stroh's interrogations. By treating Regis's language as problematic, Mrs. Stroh limited his possibilities, highlighting what it appeared he could not do and limiting opportunities to show what he could do. Paraphrasing Ladson-Billings (1994), “when students are treated as [in]competent they are likely to demonstrate [in]competence” (p. 123). This was, arguably, the case with Regis.

It is not that there was not something *different* about Regis, but these differences were not the source of the problems he experienced at school. The problem did not consist in his having learning difficulties—being deficient in verbal skills—as much as in *his living in* “a world well organized to label and disable him” (McDermott and Varenne, 1999, p. 42). As McDermott and Varenne (1999) argue,

The problems many people have in the American School stem only incidentally from what they can or cannot do and much more radically from the way they are treated by others in relation to the designation, assignment, and distribution of more or less temporary or partial difficulties interpreted as success or failure and responded to in the terms of the testing world. (pp. 134–135)

Regis's “struggle” was located in the interaction between him and

features of learning environment[s], including text genres, patterns of talk, and modes of literate expression. Struggle is not a characteristic of individual learners; a struggling reader or writer is one who is experiencing a mismatch between their preferred literate mode and the one they are being asked to communicate with in school.

Collins and Ferri (2016, p. 11).

To be clear Mrs. Stroh is not the villain here. Her interactions with Regis constructed her as a particular kind of person, too. As a primary teacher she has been deputized to police children's behavior, always on the lookout for deficiencies to be remediated. She invoked a familiar instructional script in response to Regis's perceived struggles with verbal expression made salient by his identity as a low achiever. Together Regis and Mrs. Stroh engaged in a perverse, improvisational dance mediated by institutional scripts of schooling and, in this way, they performed particular identities that made them into particular kinds of people, in Regis's case, a student with a learning problem.

But this performance goes beyond just Regis and Mrs. Stroh. Lots of people participated in the choreography of their interactions. The work of schooling is “embedded in the concerted activities of millions of people engaging a surveillance system of professionals—doctors, psychologists, lawyers, educators, and parents are all involved and at the ready before the children show up” (McDermott et al., 2006, p. 6), looking for and producing evidence of school failure. If it takes a village to raise children like Regis, it takes a culture to disable them.

Social constructivism offers a theoretical rationale for rejecting deficit views of school failure. But this is not merely a theoretical matter. Like deficit models of school failure, a social constructivist lens has implications for how schools are organized and how teachers teach. The following section takes up the implications of a social constructivist position on both instruction and how schools might be organized to accommodate the incredible diversity that exists among the student populations.

Implications: a presumption of competence

When it comes to education, theory matters, affecting both how teachers perceive their students and how students perceive themselves. The presumption that poor school achievement is an individual failure residing in the minds and bodies of failing students, for example, leads to practices designed to remediate or “fix” students. Paraphrasing Rist (1970), there is a greater tragedy than being labeled a poor learner and that is being treated like one. From a deficit perspective, being treated like a poor learner typically translates into a reductive, low-level curricula that creates failure by limiting students’ affordances for learning (Annamma et al., 2013; Horn, 2007; White, 2020; Wong, 2010). Students learn less because they are taught less, reinforcing a cycle of failure, a self-fulfilling prophecy that reinforces the initial claim that it is the student who is the problem.

As has been argued above, a social constructivist perspective rejects the position that school failure resides solely in the minds and bodies of students. The student is not the problem. Rather, the problem is the problem (see Collins and Ferri, 2016). When students produce perplexing responses, as in the example of Regis and Mrs. Stroh, the question is not, “what’s wrong with this student?” but “what’s going on here?” How is it that a child who is good at learning in other contexts is not good at learning inside the walls of schooling? (Gee, 2004). Teachers working from a social constructivist perspective begin with a presumption of competence (Biklen and Burke, 2006), “that each person, regardless of age, gender, economic circumstance, or geographic location, is constantly in the process of constructing meanings based on her or his own life experiences” (Miller, 1993, p. 56).

Two instructional principles follow from a social constructivist stance on learning failure: All learners are smart (Miller, 1993) and students learn what they are taught. If the instructional focus for low achievers is on low-level skills, that is what they will learn. They will not learn the rich, engaging practices afforded high-achieving students—unless they are taught them. Therefore, from a social constructivist perspective, what low-achieving students need most is to be afforded the same opportunities and quality of instruction—what has been referred to as high-expectation curricula (Dudley-Marling and Michaels, 2012)—as that afforded the most academically successful students. Recalling the dance metaphor used earlier in this article, the emphasis is on altering the shape of the dance—the interaction between teachers, students, the curriculum and so on—and on not merely “fixing” the dancers. As Gutiérrez (1994) has shown, even a small change in the pattern of interactions between students and teachers can have a significant impact.

A particularly striking example of high-expectation curricula with low-achieving students comes from Dudley-Marling and Michaels (2012) who describe the implementation of a high-expectation literacy curricula, Shared Inquiry, in a high-poverty, low-achieving school in New York City. Students in Lexington Elementary engaged in routine, lengthy (53 min on average), evidence-based discussions of challenging texts. Over the course of a school year, students learned to work together to make claims, cite textual evidence and, if needed, make explicit the evidentiary warrant for their claims in response to open-ended questions posed by their teachers. This practice stood in stark contrast to the district mandated literacy curriculum that focused almost exclusively on low-level skills like phonemic awareness and sound blending. After a single academic year, Lexington Elementary students showed dramatic gains on district-mandated achievement tests. More specifically, Shared Inquiry discussions created affordances that enabled students in a low-achieving, high-poverty school to display a high level of academic competence as students constructed sophisticated academic arguments while discussing challenging texts (Dudley-Marling and Michaels, 2012), contradicting the widely-held belief that cognitively demanding modes of instruction are inappropriate for low-achievers (Horn, 2007).

Other examples of high-expectation curricula with low-achieving students include Project Challenge (Chapin and O’Connor, 2012) and the Optimum Learning Environment (OLE) Project (Ruiz et al., 1996). Project Challenge is a demanding, inquiry-based mathematics curriculum emphasizing mathematical reasoning skills and implemented in low-achieving, high-poverty schools. The OLE Project, created curricula for special education students in low-achieving, bilingual schools, is informed by progressive pedagogical principles that underpin gifted education including student choice, active student engagement in learning, meaningful and authentic purposes for learning, and learning in social contexts. Both the OLE Project and Project Challenge report significant improvement in student achievement on standardized assessments (Chapin and O’Connor, 2012; Ruiz et al., 1996).

There is also a substantial body of literature supporting the efficacy of heterogeneous, de-tracked classrooms in which low-achieving students are educated alongside their higher achieving peers (Oakes, 1985/2005; Thompson, 2001). The Preuss School, for example, is a single track, college-preparatory public charter school that provides a rigorous curriculum to low-income students, with high potential but undeveloped skills, selected through lottery (Mehan, 2012). Preuss classes emphasize project-based learning and a portfolio of assessments fulfilling or exceeding the entry requirements of the University of California and California State University systems. An average of 84% of the graduates of the first classes at Preuss (2004–2009) attended four-year colleges. Preuss was also among the highest ranked high schools in the district in 2009, 2010, and 2011, outpacing many schools with a much lower proportion of students living in poverty.

Arguably, the presumption of competence that underpins de-tracking and high-expectation curricula like OLE and Project Challenge transform student learning identities—and enhance student achievement—by altering the shape of the *pedagogical dance* that makes teachers and students into particular kinds of people (see Dudley-Marling and Michaels, 2012 for other examples of high-expectation curricula). Such practices also contribute to student success by transfiguring students’ beliefs about themselves and their identities as learners (Brodeur, 2021).

Re-constructing learning problems will require more than the simple abnegation of deficit thinking in favor of challenging, transformative curricula. Low-achieving students, like all learners, will require some measure of explicit, individualized and intensive instruction (Dudley-Marling and Paugh, 2009). Low achievers, even those who have acquired formal labels like “learning disabled,” do not, however, require unique, narrowly defined, evidence-based practices based on a mythical average student (Collins and Ferri,

2016). As Collins and Ferri (2016) put it, “If someone is having difficulty reading a particular text, finding what works in a large, randomly assigned clinical trial matters less than finding what works for that person” (p. 9). Ultimately, schools must create inclusive spaces that are congenial to the range of student learning and cultural identities they bring with them to school (see Dudley-Marling and Burns, 2014 for a comprehensive discussion of inclusive classrooms).

Conclusion

Deficit thinking is a pernicious practice that situates the blame for low academic achievement solely in the minds and bodies of individual students. Believing that the problem of school failure is an individual accomplishment, the solution for learning difficulties has tended to focus on “fixing” students through curricular practices that limit students’ affordances for learning, thereby exacerbating the problem. To the degree that deficit thinking does consider broader influences, the tendency has been to implicate the language and culture of families and communities as the root causes of school failure, especially among the poor (e.g., Hart and Risley, 1995; Payne, 2005). This deficit stance simultaneously blames poor students for school failure while deflecting attention from systemic explanations for disproportionately high levels of failure in high poverty schools, places overpopulated by students of color (NAEP, 2019). Like the case for individual students outlined above, it is not the deficit perspective per se that harms poor children as much as what comes from this stance. And there is an abundance of evidence that students living in poverty are much more likely to experience a circumscribed curriculum—what Haberman (1991) referred to as a “pedagogy of poverty”—that severely limits their educational and vocational attainments (Anyon, 1980; Kozol, 2005), reinforcing racist and classist beliefs about the poor and children of color. Arguably, such disparities in curricula account for the widespread finding that, as they pass through the grades, “children living in high-poverty areas tend to fall further behind, regardless of their initial ... skill level” (Snow et al., 1998, p. 98).

A social constructivist lens exposes the systemic factors that create so much failure in schools, especially among students already burdened by discrimination and poverty. It begins with the presumption that all students are competent and a skepticism toward claims that individual or groups of children lack the innate abilities to succeed in school.

Introduction

Learning in the Disciplines reflects a convergence of research on how people learn and develop and the competencies required of an educated citizenry in the 21st century. Knowing what is no longer sufficient for effective functioning in a society in which information must be vetted and evaluated rather than merely being accepted as fact. People need to understand how knowledge is generated; how it is represented and communicated; and how to process, interpret, and evaluate new information in light of their existing knowledge and belief systems. Doing so allows people to take a critical stance toward information. These 21st century competencies align well with what is referred to as disciplinary literacy - the reading, reasoning, and argumentation practices of specialists in disciplinary content areas (e.g., [Goldman, 2012, 2015](#); [Moje, 2008, 2015](#)). However, surveys of industry employers, college instructors, and healthcare providers, as well as national and international assessments, unfortunately indicate that most citizens lack these 21st century competencies ([American College Testing, 2006](#); [Ananiadou and Claro, 2009](#); [National Alliance of Business, 2002](#); [National Assessment of Educational Progress, 2009, 2022](#); [National Center for Education Statistics, 2013, 2022](#); [National Research Council, 2012](#); [Organization for Economic Co-operation and Development, 2013](#)). These findings should not be surprising given that typical subject matter learning involves students reading to learn content rather than engaging in practices that experts in the field used to generate the content (e.g., [Goldman et al., 2016](#); [Greenleaf et al., 2001](#); [Greenleaf and Valencia, 2017](#); [Rainey and Moje, 2012](#); [Vaughn et al., 2013](#)). The result is that students do not have opportunities to engage in the literacy practices appropriate to specific disciplines or be exposed to considerations of how similar and different particular practices are across different disciplines. Nor do they have experiences learning from one another to collaboratively solve problems and innovate on traditional ways of thinking and approaching problems.

The topic of this chapter, Learning in the Disciplines, reflects an emphasis among those concerned with defining the goals of schooling to better equip individuals with the competencies 21st century society demands. This includes not only redefining what learners learn but how they come to learn it. In this chapter, a conceptual framework is presented that has proven valuable for organizing the varied kinds of disciplinary knowledge and practices that constitute what disciplinary experts know in their domain of expertise. The framework was the result of a large collaborative effort over several years to characterize the kinds of knowledge disciplinary experts bring to bear when they reason, argue, and generate new knowledge within their disciplinary communities ([Goldman et al., 2016](#)).

Assumptions underlying the conceptual framework

Two foundational assumptions underlie the framework. The first is that learning is situated in interactional spaces in which the individual and community are changing or evolving together through their joint participation ([Rogoff, 1997](#)). Knowledge is generated or constructed through interactions with others, material resources, and tools (e.g., [Vygotsky, 1978](#)). Learning happens through and with others. Learners take up practices of those they come into contact with through observation or participation in those practices ([Rogoff, 1997](#)). These interactions and observations become the basis of internalized representations and include cognitive (memory, perceptual, reasoning processes), as well as social and affective dimensions. In turn, what has become internalized shapes how learners participate in, experience, and observe subsequent interactions: how and what learners think and feel arises from complex interactions that reflect learners' cultural and contextual circumstances. Learning then is defined, in part, as the transformation of an individual's ability to participate in valued social and cultural activities. The processes by which an individual engages in practice involve emotional, motivational, and relational aspects of self, not just knowing ([Holland and Lave, 2009](#)).

Consistent with the first assumption about the nature of learning is the second: Disciplines can be conceptualized as communities of practice (Lave and Wenger, 1991) wherein the members negotiate the norms, conventions, and criteria for proposing, arguing for, establishing, and evaluating knowledge claims and the arguments put forth for them. Criteria are established for what constitutes valid and reliable inquiry practices, including patterns of logic and reasoning for connecting evidence to the claims it is intended to support (Toulmin et al., 1984). Evidence that does not meet these criteria compromises whatever claims are being made on the basis of that evidence. Members of a disciplinary community also share common epistemic commitments to the aims, goals, and purposes of argument and knowledge generation within their discipline (e.g., explanation, evaluating alternatives, proposing policies) and the representational forms used to communicate their ideas with one another (e.g., Bazerman, 1985; Shanahan et al., 2011). However, what is shared among members of a community may not be known by those outside the community. Becoming a member of a disciplinary community involves learning these norms and conventions in addition to learning specific content. Indeed, “outsiders” to the disciplinary community who do not have access to disciplinary norms and conventions often read and attempt to make sense of disciplinary information differently than intended by the disciplinary community, resulting in different interpretations (Bazerman, 2004; Goldman and Bisanz, 2002; Latour and Woolgar, 1986; Wineburg, 1991). The “insider—outsider” dichotomy is in part related to the rise in misinformation and disinformation occurring in present day society. The insider-outsider issue is one of the challenges adolescents face when they are tasked with reading specialized disciplinary texts in content area classes in order to perform discipline specific tasks (Goldman and Bisanz, 2002; Moje and O’Brien, 2001). However, instruction that focuses on the specialized ways of reading, thinking, and conveying information within a discipline is relatively rare (Alvermann and Moore, 1991). Rather, equipped with only generic reading strategies, learners often encounter unfamiliar and technical vocabulary, complex syntax, and a variety of genres within and across disciplines (Lee and Spratley, 2010). Thus, in addition to building knowledge in different content areas, they are grappling with disciplinary literacies—the oral and written reasoning, argumentation, and communication practices of the disciplines (Moje, 2008; Carnegie Council on Advancing Adolescent Literacy, 2011). In developing a conceptual framework for learning in the disciplines, our team endeavored to capture the various kinds of knowledge that disciplinary “insiders” bring to their disciplinary work, including knowledge of how disciplinary information is represented and communicated as important to the construction and generation of disciplinary knowledge. All of these define what it means to be literate and learn in a discipline.

Development of the conceptual framework for disciplinary literacies

The initial phase of building the conceptual framework for Learning in the Disciplines focused on identifying within three disciplines—science, history, and literary reading—the various kinds of knowledge that members of a disciplinary community negotiate and share in their efforts to generate new knowledge. As reported in Goldman et al. (2016), the team conducted a conceptual metanalysis of theory and research on experts in each of these three disciplinary areas (science, history, and literary reading), identified differences between experts and those engaged in learning these disciplines, and reviewed efforts that had been made to create learning environments and interventions intended to support learners in becoming more expert in these disciplines. In a second phase, we looked across the findings from the conceptual metanalyses for each discipline and asked how the disciplines were similar and how they were different. This process enabled us to generate a higher order characterization of the kinds of knowledge that we labeled Core Constructs. Disciplinary learning goals are developed by instantiating the core constructs for specific disciplines. Thus the Core Constructs constitute a conceptual framework for the disciplinary literacies involved in learning in the disciplines.

In the present context, we first summarize the major findings of the conceptual metanalyses focusing especially on characteristics of domain experts. While there are similarities in the general characteristics of experts and expertise across disciplines, instantiating how these are manifest in specific disciplinary contexts is necessary to determine what it takes to support learners in engaging in learning a discipline.

Research on expertise

Cognitive research on the nature of expertise indicates that expertise is domain specific. In their domains of expertise, experts have extensive but highly organized knowledge and strategies that are not present in those new to the discipline (See for discussion Chi et al. (1988) and Goldman et al. (1999)). It is well-established that learning is an active process where the knowledge, skills and dispositions that a learner brings to a learning task guide how they perceive and engage with new information and new tasks (See Bransford et al. (2002) for elaboration). Given the differences in the knowledge bases of domain experts and non-experts, it is not surprising that they approach domain tasks differently. The knowledge bases of experts enable them to see meaningful patterns in data, store and effectively retrieve information in response to task demands and develop more efficient problem solving strategies as compared to novices in the domain (See Goldman et al. (1999) for review). In one classic study, Sabers et al. (1991) compared expert and novice teachers’ responses to a classroom video. There were differences between them in what they noticed and how they interpreted what they did notice. The novice teachers provided simple descriptions of isolated events and made few if any

inferences about the relationship between the instruction and the students' behavior. The experts, on the other hand, paid attention to a great range of activities and their interrelationships and to what the verbalizations implied for interpreting the events shown on the video. Differences in professional perception lead to differences in problem definitions and approaches to their solutions (Seidel and Stürmer, 2014; Wolff et al., 2016).

Domain experts also display metacognitive knowledge of their learning processes, particularly with respect to detecting inconsistencies. They can provide explanations for the strategies they employ in their problem-solving efforts. For example, in one study, history experts indicated that they began reading historical documents by first ascertaining sourcing information, including when the document was produced, by whom and for what purpose. This information was critical to how they related the information to their prior knowledge and interpreted it (Wineburg, 1991, 1994). Students jumped right into reading the artifacts provided to them. In other studies, students have been found to simply summarize the content of documents rather than submitting them to critical examination or evaluating the trustworthiness and potential biases of a document (Greene, 1994). Similar differences have been observed in the sciences. Across a variety of science fields, scientists evaluate information against established criteria for reliable and valid data (e.g., Chinn and Brewer, 1996; Dunbar, 1995; Koslowski, 1996; Schauble et al., 1995). Experts' knowledge representations have also been shown to reflect deeper, principled understandings of the information in comparison to those of novices. This enables them to discern meaningful patterns in situations as diverse as chess board arrays (Chase and Simon, 1973) and physics representations (Chi et al., 1981) for chess and physics experts respectively.

Some might argue that domain experts are just smart people and smarter than the non-experts to whom they have been compared in the research studies. This is not the case. Outside of their domain of expertise, they display noticing, problem solving, and metacognitive processes different from those they display within their area of expertise. For example, experts reading outside their fields display different approaches than when reading within their area of expertise (Bazerman, 2004). In other words, they perform like non-experts in domains beyond their own.

From a situated, sociocultural perspective, experts are members of specific communities of practice that have evolved and share physical, social, and cognitive resources that constitute the cultural context of the community (Danish and Gresalfi, 2018; Greeno and Engstrom, 2014). Experts are very good at organizing and structuring their time and space to capitalize on the cultural resources and tools at their disposal as members of their communities of practice (Hutchins, 1995; Kirsh, 1995). It is also the case that no two situations of knowledge application are ever identical. Experts are often adept at adapting what they know to the particularities of the performance situation. This is especially the case for expert teachers (Markauskaite and Goodyear, 2017).

Core constructs for learning in the disciplines

What emerged from the analyses of expertise in each of the three disciplines were discipline-specific clusters of the kinds of knowledge that experts relied on when reading, reasoning, solving problems, constructing and conveying evidence-based arguments in their fields. We organized the clusters for each discipline into five higher-order categories of what we called disciplinary core constructs:

- Epistemology: Beliefs about the nature of knowledge and the nature of knowing. What counts as knowledge? How do we know what we know?
- Inquiry Practices, Reasoning Strategies: Ways in which claims and evidence are established, related, and validated
- Overarching concepts, themes, principles, frameworks: Foundational concepts, ideas, reasoning principles, and assumptions. These serve as a basis for warranting, justifying, legitimizing connections between evidence and claims.
- Forms of information representation/types of texts: Types of texts and media (e.g., traditional print, oral, video, digital) in which information is represented and expressed.
- Discourse and language structures: The oral and written language forms in which information is expressed.

Over the course of our work with these constructs, we came to see epistemology as central, providing purpose and motivation to the ways in which inquiry was conducted; the reasoning principles that were invoked; and the forms in which information was represented, expressed, examined, and critiqued, and negotiated in and through oral and written discourse and language structures. Differences in the norms and conventions of different disciplinary communities arise in part from epistemological commitments about the nature and purposes of the knowledge generated, that is what constitutes the disciplinary knowledge base. Furthermore, the epistemic aims, values, and goals of a discipline have implications for inquiry questions and the practices associated with knowledge generation, reasoning, and representation (Andriessen, 2006; Braaten and Windschitl, 2011; Chinn et al., 2011; Gee, 1992; Hillocks, 2011; Megill, 1989; Osborne, 2002; Pearson et al., 2010; Wineburg, 2001). In literature for example, a central epistemic aim of literary interpretation is exploration of the human condition through multiple perspectives, including philosophical, moral, social, political, economic, and cultural contexts of the human experience. Literature invites dialogic interaction among readers; it is open to multiple interpretations even as readers seek to understand authorial intent. Accordingly, literary epistemology values attention to both content and form as critical windows into authorial messages. Indeed, much of literary criticism is concerned with the

relationship between meaning and intentional decisions that authors make about character types, plot structures, and specific language choices as cues to authorial intent (e.g., [Rabinowitz, 1987](#)). For example, patterns of word or phrase repetitions or the occurrence of the unexpected are features of literary works that suggest possible figurative uses of language and the need to go beyond the literal meaning to entertain symbolic or metaphoric interpretations (For discussion see [Lee et al., 2016](#)).

On the other hand, in science, the epistemic aims and associated inquiry questions are often about explaining causes of phenomena in the natural and designed worlds ([Rutherford and Ahlgren, 1990](#)). Scientists accrue evidence for and against potential explanations of science phenomena, putting forward databased arguments for peer critique and justifying the viability of their explanatory models by appealing to existing bodies of scientific principles ([Berland and Reiser, 2009](#); [Ford and Wargo, 2012](#)). The nature of scientific knowledge is tentative and subject to revision in the face of new empirical evidence that may reflect changes and advances in technology and measurement methods. Science inquiry practices are consistent with this epistemological orientation. New investigations are often generated through careful reading of published data sets and methods and are scrutinized and evaluated for reliability and convergence with other findings (e.g., [Chinn and Malhotra, 2002](#); [Duschl and Osborne, 2002](#)).

In contrast, virtually all historians agree that the epistemic purpose of history is the generation of interpretations of the past based on admittedly incomplete traces, also known as primary sources (e.g., [Megill, 1989](#)). Both the traces of the past and interpretations of them are acknowledged as human constructions that can be questioned, critiqued, and contested ([Lee, 2005](#); [Seixas, 2010](#)). Inquiry into the past therefore uses practices for comparing across primary source traces and contextualizing the information in these sources in what else was going on at the time. These inquiry practices help establish the credibility and reliability of primary sources (e.g., [Leinhardt and Young, 1996](#); [Wineburg, 1991](#)). Inquiries into the past are limited by the incompleteness of the historical record and an important question is whose voice(s) are missing. Historical knowledge is provisional and subject to revision based on new evidence. These characteristics of historical knowledge often result in competing and contested interpretations. Historical inquiry requires reading and reasoning practices that closely attend to metadata related to particular sources as well as points of convergence and divergence across multiple representational levels of meaning in service of generating a coherent interpretive model of the past, a goal that cannot always be reached (e.g., [Britt et al., 2018](#); [Reisman, 2012](#); [Rouet and Britt, 2011](#)).

Differences among disciplines in epistemic aims and goals produce differences in the essential questions of each discipline; in the practices that are followed with respect to gathering, vetting, and selecting information to address the questions; and in the forms and content that constitute products of the disciplinary inquiry ([Goldman, 2018](#)). More specifically, differences in the products of inquiry imply differences in the questioning, data gathering, and reading and reasoning practices needed for problem solving and inquiry in each discipline. The inquiry processes must be situated and attuned to the ways in which information is represented, the goals of disciplines, and the discourse forms of specific disciplines so that comprehension, sense-making and problem-solving focus on what matters and what counts for addressing disciplinary inquiry questions. Across disciplines however, the practices can be described at a general level: careful attention to data—closely reading the data; synthesis and analysis within and across different data sets that were gathered; creation of claim–evidence–reasoning structures; use of interpretive frameworks, principles, and criteria; evaluation of reliability and justification; and appreciation for the epistemology of the discipline. What it looks like to engage in these practices is what varies from discipline to discipline.

To illustrate the nature of differences from discipline to discipline in how the core constructs are instantiated, [Table 1](#) shows the results of the specification of core constructs for literature/literary reading, science, and history. [Goldman et al. \(2016\)](#) provide the theoretical and empirical grounding for these instantiations. Note that one limitation of the effort in science was that we focused primarily on text-based inquiry rather than encompassing expertise in bench science. However, we intend the phrase text to refer to the broad array of forms in which data and models are generated and conveyed in the sciences, including diagrams, schematics, data visualizations (e.g., figures, tables), photographs, and so forth. Expertise in science entails using these various “text” forms to make sense of observational, historical, and experimentally-generated information. The specifics of how the core constructs were manifest within each discipline reflects the differences among the disciplines in their epistemological aims and values; inquiry practices; big ideas, principles, and interpretive outcomes; and how they are represented and communicated.

Clearly, the instantiation of the core constructs is a heuristic for approaching the analysis of a discipline in terms of its aims and goals, inquiry methods, and so forth. Variations on the specifications provided in [Table 1](#) would be expected for any of the various subdisciplines within each of the very large disciplinary categories shown in [Table 1](#). Furthermore, the instantiations in [Table 1](#) reflect a largely Western perspective on these three disciplines, especially regarding the epistemic goals and aims and the inquiry methods. The process of interrogating each of these core constructs is itself a situated learning activity occurring in the cultural contexts of those engaged in the analysis. Thus, alternative instantiations of these three disciplinary areas can be anticipated. The dialogic that results from considering such alternatives can be expected to yield fruitful understandings of the ways in which established norms and conventions of disciplinary communities are themselves time and place bound and should be expected to evolve. The community not only shapes but is shaped by the individual members. As membership in disciplinary communities becomes more diverse, the perspectives they bring should naturally result in the re-negotiation of norms and conventions for generating new disciplinary knowledge and specifications of core constructs. In addition, learners come to the disciplinary canon with ways of making sense in their everyday worlds (e.g., [Moll et al., 1992](#)). These everyday sensemaking practices are resources that can act as pathways into disciplinary learning practices using approaches such as cultural modeling ([Lee, 2007](#)).

Table 1 Highlights of instantiations of core constructs literature, science, and history.

Epistemological Aims and Values		
Literature/Literary Reading	Science: Text-based Inquiry	History
Literature as a window into interrogating the human experience including the social, political economic, and cultural contexts of the world. Literary texts are open to dialogue among communities of readers within and across time. Literary critique values attention to both content and form, and investigates how decisions by authors regarding structure and language use influence meaning.	Explanations of the natural and engineered worlds expressed as models and theories that are • approximations and have limitations. • based on sound empirical data • socially constructed • meet criteria of parsimony, and logical cohesion. • subject to revisions with successive empirical efforts that reflect changes in technology, theories and paradigms, and cultural norms.	Claims about the past are based on a historical record that is inherently incomplete, conflicting, and obscure, and therefore provisional and contestable. Historians make interpretive arguments about the past based on the historical record but from their own perspectives.
Inquiry Practices, Reasoning Strategies		
Literature/Literary Reading	Science: Text-based Inquiry	History
Infer from details within texts • Plot sequence and causal links between events, actions • Characters motivations and psychological states, and relationships among of characters. • Structural generalizations about how inferred meanings are achieved rhetorically • Generalizations the reader argues the author is making about the world beyond the text itself Evaluate how rhetorical strategies are employed to help shape reader's response. To construct interpretations, draw on prior knowledge of • Social milieu of the text • Human intentionality • Moral and philosophical	Scientific knowledge is built by: • Developing coherent, logical explanations, models or arguments from evidence • Advancing and challenging explanations • Converging/corroboration of evidence • Comparing/integrating across sources and representations • Evaluating of sources and evidence in terms of scope, reliability, and extent to which it accounts for evidence.	Historians investigate questions, interrogate the historical record, or analyze historical interpretations through • Sourcing • Contextualization • Corroboration • Questioning inclusiveness (what perspectives, sources, data are included or omitted) • Questioning coherence • Avoiding logical and reasoning fallacies

(Continued)

Table 1 Highlights of instantiations of core constructs literature, science, and history.—cont'd

precepts • Related literary and non literary texts • Other works by the author		
Overarching Concepts, Themes, Principles		
Literature/Literary Reading	Science: Text-based Inquiry	History
Readers construct interpretations of literary texts using belief systems and principles that reflect • Morality and philosophy • Historical contexts • Traditions of critical theory (e.g., Reader response, feminist, New Criticism, Post Structuralism) • Intertextuality, including relations among literary texts, between literary texts as well across literary and historical, sociological, philosophical texts	Scientists connect evidence to claims using • Cross-cutting concepts (patterns; cause and effect; scale, proportion and quantity; systems and system models; energy and matter in systems; structure and function; stability and change of systems). • Disciplinary core ideas in the physical sciences, earth and space sciences; life sciences; and engineering, technology, and applications of science	Historians draw on a variety of interpretive frameworks: • Societal systems (political, social, economic, technological, geographic) • Relational (chronological, contingent, causal, coincidental, chance) • Change over time • Thematic (migratory processes, industrialization, power relations) • Complex systems
Forms of information representation/types of texts		
Literature/Literary Reading	Science: Text-based Inquiry	History
Prototypical genres and ways of structuring plots; kinds of prototypical protagonists. • Generic genres (e.g. stories, poems, dramas) • Specialized poetic genres (e.g. haiku, ballad, sonnet) • Exemplar plot structures (e.g., coming of age, science fiction, fable, satirical works, myth, magical realism) • Exemplar Protagonists (tragic hero, antihero, mythic hero, trickster,)	Scientific texts may have different explanatory purposes (e.g., cause effect, correlation, comparison, process sequence, chronology, enumeration, description). Science texts convey meaning with multiple representations (e.g., verbal,digital, equations, graphs, tables, simulations, flowcharts, schematics, videos)types of sources (e.g., bench notes, refereed journal articles, textbooks, websites, blogs).	Texts types in history are • Primary sources that include all texts from the period of study (e.g., autobiography, memoir, fiction, news story , editorial, political cartoon, art, graphic novel, video, legal documents). • Secondary and tertiary sources (e.g., biography, historical fiction, data tables, textbook, editorial, polemic essay, political map) History texts appear in a range of media, including traditional print, radio, TV, video, and hypermedia.

Table 1 Highlights of instantiations of core constructs literature, science, and history.—cont'd

Discourse and language structures		
Literature/Literary Reading	Science: Text-based Inquiry	History
How author's selection and sequence of action, dialogue and description create an imaginary world into which the reader is invited through the manipulation of language. Major ways of using language are • Imagery: Language used to create a visual representation and invite emotional response (e.g., use of descriptions, metaphor, simile) • Figuration: Language used to invite a figurative interpretation beyond the literal (e.g., symbolism, irony, satire) • Problems of point of view: Who is speaking; reliability; authorial versus narrative audience; relation of narrator's point of view to the author (e.g., omniscient narrator, unreliable narrator, multiple narrators) • Rhetorical strategies and patterns (e.g., parallelism, contrast, repetition, understatement, exaggeration, allusion, dialogue typography, privileged placement)	Science texts contain • distinctive grammatical structures (e.g., nominalizations, passive voice). • technical and specialized expressions. • signals to the degree of certainty, generalizability, and precision of statements. Argumentation is a scientific discourse practice in which evidence is used to support knowledge claims, and scientific principles and methods are used as warrants.	Structure of historical arguments can be • descriptive (<i>What was the case?</i>) • explanatory (<i>Why was it the case?</i>) • narrative (both descriptive and explanatory structures) Linguistic features of history texts mark conventions of chronology, periodization, perspective, theme and topic. History texts include accurate and thorough documentation of sources, usually in the form of footnotes or notes. Conventions for claim and evidence presentation in oral and written forms include • One-sided, two-sided arguments, multi-sided • Two-sided, multi-sided refutational arguments • Implicit arguments (embedded in descriptive and narrative structure) • Oral arguments (debates, discussions, conversations)

Core constructs: a conceptual tool for emergent disciplines

The complexity of the 21st century is giving rise to the emergence of new disciplinary areas, often beginning in multi- or inter-disciplinary collaborations. The Core Constructs Disciplinary Literacies framework can serve as a tool for explicitly attending to the epistemological commitments of constituent disciplines in multi- and inter-disciplinary work and for negotiating the aims and goals of emergent, integrated disciplines. Such an effort would lay the groundwork for considering the inquiry methods, big ideas and principles, representational forms and rhetorical structures that characterize the knowledge base of emergent disciplines. There is a clear need for this in that there is already a robust movement for integrated STEM as an approach to address “conditions that require the application of knowledge and practices from multiple STEM disciplines to learn about or solve transdisciplinary problems” (Nadelson and Seifert, 2017, p. 221). Bioinformatics (biological sciences and informatics/data sciences) and earthquake engineering (seismology and engineering) (Cavlazoglu and Tuessy, 2017) are two examples. Attention to the types of knowledge being brought together in such integrations is critical to understanding what new learning is required on the parts of experts in the “combining” disciplines in order to work together productively.

It is important to attend to these issues because knowledge gaps between the home disciplines and the integrated disciplines can threaten the success of integrated disciplines. Representing the core constructs of the home disciplines can be one way to mitigate unproductive, and facilitate fruitful, interactions and the emergence of new disciplinary communities by explicating the knowledge demands of the integrated discipline in comparison to those of the origin/home disciplines. Specifying the inquiry practices, representational literacies, and epistemic commitments of interdisciplinary areas and integrated disciplines is a necessary first step toward preparing professional learning experiences that enable teachers to teach these disciplines. For example, in the case of bioinformatics, knowledge gaps between biological sciences and bioinformatics include environmental science, public health, statistics, and computer science content along with practices for working with real-world messy data, a type of data not typically covered in high school biology courses (Kelley and Knowles, 2016; Kjølvik and Schultheis, 2019). Yoon et al. (2022) document the challenges they confronted when they focused solely on preparing teachers to implement a bioinformatics curriculum without also providing the biology teachers with opportunities to delve in-depth into the gap areas between biology and bioinformatics.

In sum, integrated disciplines and interdisciplinary work in general reflect new communities of practice in which the members need to explore and negotiate their epistemic commitments, consider compatibilities and incompatibilities in the inquiry methods of the originating fields, and learn each other's representational forms and rhetorical structures. This is especially so for those tasked with interdisciplinary teaching and the teaching of integrated disciplines to high school and college students.

Value-added of the conceptual framework for learning in the disciplines for designing adaptive instruction in the 21st century

Periodically, and especially over the last dozen years, frameworks and standards have emerged in efforts to redefine the goals of schooling to reflect the needs of 21st century society, especially to engage learners in authentic disciplinary practices of knowledge generation. Examples of these include the Common Core State Standards (Council of Chief State School Officers, 2010), Next Generation Science Standards (Next Generation Science Standards Lead States, 2013), the 3C Framework in Social Studies (National Council for the Social Studies, 2013), and PISA (Organization of Economic and Cultural Development, 2013). The substance of such standards and frameworks drew heavily on identifying the important ideas and principles in specific disciplinary domains as well as the practices disciplinary experts engaged in to generate this content. However, in and of themselves standards are inadequate to accomplish the transformation in classroom instruction that is needed to prepare 21st century citizens. This is because to be useful in guiding instruction, standards need to be unpacked and translated into learning processes and outcomes that can provide visible evidence relevant to learning goals (Shephard et al., 2009). Goals and evidence need to be calibrated to reflect developmentally appropriate performances and trajectories of such performances over time. Too frequently, insufficient attention is paid to this unpacking process and standards become the learning goals; instructional activities are keyed to specific standards and the purpose of the activity is to teach the standard, with little attention devoted to how different standards connect or are related to the overarching goals of the discipline. The result is often disconnected and disjointed with students having no greater grasp of the practices of the discipline and how knowledge is generated than when instruction focused on reading and memorizing "known" disciplinary content from a textbook for purposes of reproducing that information on outcome assessments.

The Conceptual Framework for Learning in the Disciplines outlined in this chapter has proven to be a useful tool for engaging educational practitioners in a process of unpacking standards in English Language Arts, Science and History. It provided them with an organizational structure that allowed them to move from teaching to the standards to building instructional units that were motivated by essential questions of the discipline—that addressed the aims and goals of the disciplinary inquiry using practices authentic to the discipline, albeit at developmentally tractable levels (e.g., Goldman et al., 2019; Levine et al., 2019). The instructional designs explicitly introduced students to the purposes of historical, literary, or scientific inquiry by making visible to middle and high school students the essential questions each discipline aimed to address as well as the reading, thinking, and reasoning inquiry practices that could be employed to address the essential questions. Example units can be accessed under publications and case library at www.projectreadi.org. Collaboration and discussion became functional participation structures for engaging in the complexities that arose in the inquiry, complexities that could easily overwhelm an individual learner. As students wrestled with multiple perspectives, conundrums, and inconsistencies they argued to make sense and learned important disciplinary content, principles, and practices in the process. Standards were integrated and incorporated into a context of meaningful, motivating and intellectually challenging disciplinary work. Teachers consistently reported that exploring their discipline using the Core Constructs of the framework gave them opportunities to both access their own inquiry practices and deepen their understanding of the epistemic commitments of the discipline (e.g., Goldman et al., 2022; Goldman and Popp, in press; Hall and Goldman, 2022; Hall et al., 2022; Ko et al., 2022). They were then able to re-purpose classroom teaching and learning to more closely reflect disciplinary purposes and dialogic practices, both critical to supporting the development of citizens who can critically analyze and evaluate information.

Conclusion

Now in the midst of the third decade of the 21st century, the need for citizens to be able to critically analyze and evaluate information is obvious. We no longer live in the world that existed in 1897 when Adolph Ochs adopted the slogan for the New York Times "All the news that's fit to print" as a commitment to impartial news reporting. In contemporary times, the increasing

dominance of social media as a main source of information underscores the need to educate citizens who can adopt a critical stance toward the information that confronts them in their personal, professional, and civic lives. The Conceptual Framework for Learning in the Disciplines provides a basis for building classroom instruction that supports the development of the competencies needed to do so.
